[*95·63 . *93·36]

The following example may illustrate the scope of *95·65. Let R, S be the generating relations of two well-ordered series, neither of which has a last term. Put $P = R \dot{-} R^2 . Q = S \dot{-} S^2$. Then P is the relation of immediately preceding in the R-series, and Q is the relation of immediately preceding in the S-series. We shall have

$$P, Q \in 1 \to 1 . \text{G'}P \subset \text{D'}P . \text{G'}Q \subset \text{D'}Q.$$

Also, except in certain exceptional cases, $\overrightarrow{B}\text{'}P$, $\overrightarrow{B}\text{'}Q$ are the first derivatives of the two series (including the first terms of the two series).

$$\text{"}C\text{'}P = \breve{P}_*\text{''}\overrightarrow{B}\text{'}P\text{"}$$

states that, starting from any term of the series and going backwards, a finite number of steps will bring us to a member of the first derivative, which is true. Hence, by *95·65, neglecting certain exceptional cases, we arrive at the result that if the first derivatives of two well-ordered series have the same cardinal number of terms, then the series themselves have the same cardinal number of terms. This proposition can of course be proved otherwise; the above is merely mentioned as an illustration of the results of *95·65.

This proposition and *94·53 or *94·54 together reconstitute the Schröder-Bernstein theorem (*73·88). For, in virtue of *93·274·275 and *73·71, they together give

$$R, S \in 1 \to 1 . \mathrm{Cl}{`}R \subset \mathrm{D}{`}S . \mathrm{Cl}{`}S \subset \mathrm{D}{`}R . \supset . C{`}(R \mid S) \,\mathrm{sm}\, C{`}(S \mid R),$$

and with this hypothesis

$$C{`}(R \mid S) = \mathrm{D}{`}R . C{`}(S \mid R) = \mathrm{D}{`}S.$$

$*96$. ON THE POSTERITY OF A TERM

Summary of $*96$.

By the "posterity" of a term with respect to a relation R we mean the class $\overleftarrow{R_*}`x$. In the present number, we shall be chiefly concerned with the relation $(\overleftarrow{R_*}`x) \upharpoonright R$, *i.e.* the relation R confined to the posterity of x. We shall also be concerned with $(\overleftarrow{R_*}`x) \upharpoonright R_*$ and $(\overleftarrow{R_*}`x) \upharpoonright R_{\text{po}}$, which, as is proved in $*96 \cdot 13$, are respectively

$$\{(\overleftarrow{R_*}`x) \upharpoonright R\}_* \text{ and } \{(\overleftarrow{R_*}`x) \upharpoonright R\}_{\text{po}}.$$

The most interesting case is when $R \in \text{Cls} \to 1$. In this case, $\overleftarrow{R_*}`x$ is in general shaped like a $Q$, with $x$ at the tip of the tail; that is, $\overleftarrow{R_*}`x$ may be divided into two parts, the first an open series, the second a closed series. If y is the junction of the two, we shall have

$$xR_*z \,.\, zR_{\text{po}}y \,.\, \supset \,.\, \sim (zR_{\text{po}}z),$$

$$yR_*z \,.\, \supset \,.\, zR_{\text{po}}z;$$

in fact, $\qquad (\exists P) : P \in \text{Pot}`R : yR_*z \,.\, \supset_z \,.\, zPz.$

We have also, when $R \in \text{Cls} \to 1$,

$$y, z \in \overleftarrow{R_*}`x \,.\, \supset : yR_*z \,.\, \vee \,.\, zR_*y.$$

It thus appears that $\overleftarrow{R_*}`x$ is divided into two parts, the first consisting of those terms $z$ for which $\sim (zR_{\text{po}}z)$, the second of those for which $zR_{\text{po}}z$. The first wholly precedes the second; the first exists if $\sim (xR_{\text{po}}x)$, the second if $\dot{\exists} ! \{(\overleftarrow{R_*}`x) \upharpoonright R_{\text{po}} \dot{\cap} I\}$. Every term in $\overleftarrow{R_{\text{po}}}`x$ has one and only one immediate predecessor, except the term (if it exists) at the junction of the tail and circle of the Q; this term has just two immediate predecessors, one in the tail and one in the circle. But if either the tail or the circle is null, then every term in $\overleftarrow{R_{\text{po}}}`x$ has only one immediate predecessor, and therefore

$$(\overleftarrow{R_*}`x) \upharpoonright R \in 1 \to 1.$$

Put $\qquad I_R`x = \overleftarrow{R_*}`x \cap \hat{z}(zR_{\text{po}}z) \quad \text{Dft}$

$$J_R`x = \overleftarrow{R_*}`x \cap \hat{z}\{\sim (zR_{\text{po}}z)\} \quad \text{Dft}$$

(these definitions being only to apply within $*96$). Then $J_R`x$ is the open part of the series $\overleftarrow{R_*}`x$, and $I_R`x$ is the circular part. The open part wholly precedes the circular part, provided $R \in \text{Cls} \to 1$; *i.e.*

$$R \in \text{Cls} \to 1 \,.\, \supset \,.\, J_R`x \subset p`\overrightarrow{R_{\text{po}}}``I_R`x.$$

If J_R'x and I_R'x both exist, J_R'x has a last term, say y. The successor of this term, $\breve{R}$'y, is the only term in $\overleftarrow{R_*}$'x which has two immediate predecessors in $\overleftarrow{R_*}$'x, namely y and $\breve{\iota}$'$(I_R$'$x \cap \overrightarrow{R}$'$\breve{R}$'$y)$.

The most important applications of the propositions of the present number are in the theory of finite and infinite, both cardinal and ordinal. When R is many-one, then if I_R'x exists, or, more generally, if J_R'x has a last term, $\overleftarrow{R_*}$'x is a finite class, *i.e.* what we shall call a "Cls induct" (cf. $*120$). That is, we have

$$\vdash : R \epsilon \mathrm{Cls} \rightarrow 1 \,.\, \mathrm{E} \,!\, \max_R\text{'}J_R\text{'}x \,.\, \supset \,.\, \overleftarrow{R_*}\text{'}x \epsilon \mathrm{Cls\ induct}.$$

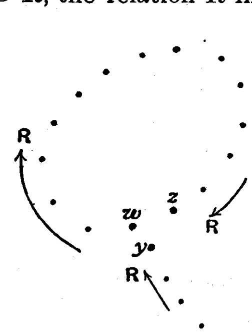
If J_R'x exists, but has no last term, $\overleftarrow{R_*}$'x is a *progression* (cf. $*122$) when its terms are arranged in the order generated by R. That is, giving to $\aleph_0$ and ω the meanings given by Cantor (cf. $*123$ and $*263$), and using "Prog" for the class of one-one relations which generate progressions, we have

$$\vdash : R \epsilon \mathrm{Cls} \rightarrow 1 \,.\, \sim \mathrm{E} \,!\, \max_R\text{'}J_R\text{'}x \,.\, \exists \,!\, J_R\text{'}x \,.\, \supset \,.$$
$$\overleftarrow{R_*}\text{'}x \epsilon \aleph_0 \,.\, (\overleftarrow{R_*}\text{'}x) \upharpoonright R \epsilon \mathrm{Prog} \,.\, (\overleftarrow{R_*}\text{'}x) \upharpoonright R_{\mathrm{po}} \epsilon \omega.$$

Another very important proposition in the proof of which the present number is useful is $*121{\cdot}47$, which proves that if R is either one-many or many-one, and a and z are any two terms whatever, then $\overleftarrow{R_*}$'$a \cap \overrightarrow{R_*}$'$z$ (which we call the "interval" from a to z) is always a finite class. The proof that progressions are well-ordered series depends upon the propositions of this number, since it uses $*122{\cdot}23$, which depends upon $*96{\cdot}52$.

The present number begins with a series of propositions (ending with $*96{\cdot}16$) on $\alpha \upharpoonright R_{\mathrm{po}}$ and $\alpha \upharpoonright R_*$, both in general and when $\alpha = \overleftarrow{R_*}$'$x$. We then proceed to a few propositions ($*96{\cdot}2$—$\cdot 25$) on $(\overleftarrow{R_*}$'$x) \upharpoonright R$ when $R \epsilon 1 \rightarrow \mathrm{Cls}$; with the exception of $*96{\cdot}24$, these propositions are all used in the cardinal theory of finite and infinite. They are, however, less important than the subsequent propositions, which are concerned with $\overleftarrow{R_*}$'x when $R \epsilon \mathrm{Cls} \rightarrow 1$.

If R is a many-one relation, and x is a member of D'R, the relation R in general arranges $\overleftarrow{R_*}$'x (*i.e.* the posterity of x) in a figure such as is here given. The relation R holds between each dot and the next, starting from x, and travelling round the circle in the sense indicated by the arrow. The dots from x to y constitute J_R'x, and the dots in the circle constitute I_R'x. y is the last term of J_R'x, *i.e.* $\max_R$'J_R'x; w is $\breve{R}$'y, and z is $\breve{\iota}$'$(\overrightarrow{R}$'$w \cap I_R$'$x)$, or, what comes to the same thing, $\{(I_R$'$x) \upharpoonright R\}$'w. w is the only term which has more than one immediate predecessor in $\overleftarrow{R_*}$'x; w always



exists if neither $J_R\text{‘}x$ nor $I_R\text{‘}x$ is null, and conversely, if w exists, neither $J_R\text{‘}x$ nor $I_R\text{‘}x$ is null. The proof of these propositions is long; the following are useful stages in the proof.

If xRx, the whole posterity of x is x itself (∗96·33); if xRy and yRx, x and y constitute the whole posterity of x (∗96·331), and so on. The successors of members of $I_R\text{‘}x$ belong to $I_R\text{‘}x$ (∗96·341), and the predecessors of members of $J_R\text{‘}x$, if they belong to $\overleftarrow{R_*}\text{‘}x$, belong to $J_R\text{‘}x$ (∗96·351). (It should be observed that, since R is only assumed to be many-one, not one-one, every member of $\overleftarrow{R_*}\text{‘}x$ may have any number of predecessors which do not belong to $\overleftarrow{R_*}\text{‘}x$.) We have a series of propositions, beginning with ∗96·4, which deal with the hypothesis $yRw \,.\, zRw$. We prove (∗96·42) that if $yRw \,.\, zRw$ and $yR_{\text{po}}z$, then $zR_{\text{po}}z$, *i.e.* z belongs to $I_R\text{‘}x$. We prove (∗96·431) that $J_R\text{‘}x$ wholly precedes $I_R\text{‘}x$; that $(J_R\text{‘}x) \upharpoonleft R$ and $(I_R\text{‘}x) \upharpoonleft R$ are both one-one (∗96·45), so that if $yRw \,.\, zRw \,.\, y \neq z$, one of y and z must belong to $J_R\text{‘}x$ and the other to $I_R\text{‘}x$ (∗96·441). Hence it follows (∗96·453) that if either $xR_{\text{po}}x$ (in which case $J_R\text{‘}x = \Lambda$) or $(\overleftarrow{R_*}\text{‘}x) \upharpoonleft R_{\text{po}} \subset J$ (in which case $I_R\text{‘}x = \Lambda$), then $(\overleftarrow{R_*}\text{‘}x) \upharpoonleft R$ is a one-one relation. (This proposition is used twice in the cardinal theory of finite and infinite, namely in ∗121·43 and ∗122·17.) Hence we arrive at the proposition (∗96·47) that if two different members y and z of $\overleftarrow{R_*}\text{‘}x$ both immediately precede a term w, then one of y and z (say y) is the last term of $J_R\text{‘}x$, w is its immediate successor and z is the immediate predecessor of w in $I_R\text{‘}x$, *i.e.* we have

$$y = \max_R\text{‘}J_R\text{‘}x \,.\, w = \breve{R}\text{‘}\max_R\text{‘}J_R\text{‘}x \,.\, z = \{(I_R\text{‘}x) \upharpoonleft R\}\text{‘}\breve{R}\text{‘}\max_R\text{‘}J_R\text{‘}x.$$

Thus y, z, w are unique if they exist. We prove next (∗96·475) that y, z, w exist when, and only when, neither $I_R\text{‘}x$ nor $J_R\text{‘}x$ is null.

It follows from the above propositions that if R is one-one, either $I_R\text{‘}x$ or $J_R\text{‘}x$ must be null (∗96·491), *i.e.* the posterity of a term is either an open series or a cycle, and cannot have the Q-shape.

$$y = \max_R{}^{\backprime}J_R{}^{\backprime}x . w = \breve{R}{}^{\backprime}\max_R{}^{\backprime}J_R{}^{\backprime}x . z = \{(J_R{}^{\backprime}x) \upharpoonright R\}{}^{\backprime}\breve{R}{}^{\backprime}\max_R{}^{\backprime}J_R{}^{\backprime}x$$

Dem.

$\vdash . *96\cdot441\cdot102 . *71\cdot361 . \supset$

$\vdash : \text{Hp} . \supset . w \in I_R{}^{\backprime}x . w = \breve{R}{}^{\backprime}y .$

[$*96\cdot461$] $\supset . y = \max_R{}^{\backprime}J_R{}^{\backprime}x . w = \breve{R}{}^{\backprime}\max_R{}^{\backprime}J_R{}^{\backprime}x$ (1)

$\vdash . *96\cdot45 . \supset \vdash : \text{Hp} . \supset . z = \{(I_R{}^{\backprime}x) \upharpoonright R\}{}^{\backprime}w$ (2)

$\vdash . (1) . (2) . \supset \vdash . \text{Prop}$

The above proposition, since it exhibits y, z, w as functions of x and R, shows that there is at most one w in $\overleftarrow{R_*}{}^{\backprime}x$ having more than one immediate predecessor, and that this one has exactly one immediate predecessor in $J_R{}^{\backprime}x$ and one in $I_R{}^{\backprime}x$. (These results require $*96\cdot441$, in addition to $*96\cdot462$.) Thus we arrive at the following proposition:

$*96\cdot47$. $\vdash :. R \in \text{Cls} \to 1 . y, z \in \overleftarrow{R_*}{}^{\backprime}x . yRw . zRw . y \neq z . \supset : w = \breve{R}{}^{\backprime}\max_R{}^{\backprime}J_R{}^{\backprime}x :$

$$y = \max_R{}^{\backprime}J_R{}^{\backprime}x . z = \{(I_R{}^{\backprime}x) \upharpoonright R\}{}^{\backprime}\breve{R}{}^{\backprime}\max_R{}^{\backprime}J_R{}^{\backprime}x . \lor .$$

$$z = \max_R{}^{\backprime}J_R{}^{\backprime}x . y = \{(I_R{}^{\backprime}x) \upharpoonright R\}{}^{\backprime}\breve{R}{}^{\backprime}\max_R{}^{\backprime}J_R{}^{\backprime}x$$

[$*96\cdot441\cdot462$]

We still have to prove

$R \in \text{Cls} \to 1 . \exists ! J_R{}^{\backprime}x . \exists ! I_R{}^{\backprime}x . \supset . (\exists y, z, w) . y, z \in \overleftarrow{R_*}{}^{\backprime}x . yRw . zRw . y \neq z,$

or, what comes to the same thing because of $*96\cdot441$,

$R \in \text{Cls} \to 1 . \exists ! J_R{}^{\backprime}x . \exists ! I_R{}^{\backprime}x . \supset . (\exists y, z, w) . y \in J_R{}^{\backprime}x . z \in I_R{}^{\backprime}x . yRw . zRw.$

This is effected in the following propositions.

$*96\cdot472$. $\vdash : R \in \text{Cls} \to 1 . \exists ! J_R{}^{\backprime}x . \exists ! I_R{}^{\backprime}x . \supset . (\exists y) . y \in J_R{}^{\backprime}x . \breve{R}{}^{\backprime}y \in I_R{}^{\backprime}x$

Dem.

This proposition is used in *122·23.

$*97$. ANALYSIS OF THE FIELD OF A RELATION INTO FAMILIES

Summary of $*97$.

In this number, we consider not only the posterity of a term, but the ancestry and posterity together, *i.e.* $\overrightarrow{R_*}\text{‘}x \cup \overleftarrow{R_*}\text{‘}x$. We put

$$\overleftrightarrow{R}\text{‘}x = \overrightarrow{R}\text{‘}x \cup (\iota\text{‘}x \cap C\text{‘}R) \cup \overleftarrow{R}\text{‘}x \quad \text{Df.}$$

Thus the whole family of a term, *i.e.* its ancestry and posterity together, is $\overleftrightarrow{R_*}\text{‘}x$. The most important case here is when $R \in 1 \to 1$; in this case families are mutually exclusive, *i.e.* we have

$$\vdash : R \in 1 \to 1 \,.\supset .\, \overleftrightarrow{R_*}\text{“}C\text{‘}R \in \text{Cls ex}^2\text{ excl.}$$

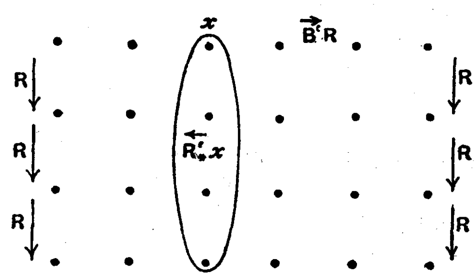
In case $R \in 1 \to 1$ and y belongs to a family which has a beginning, *i.e.* in case $\exists ! \overleftrightarrow{R_*}\text{‘}y \cap \overrightarrow{B}\text{‘}R$, the whole family of y consists of the posterity of the beginning, *i.e.* we have

$$\vdash : R \in 1 \to 1 \,.\, xBR \,.\, xR_*y \,.\supset .\, \overleftrightarrow{R_*}\text{‘}y = \overleftarrow{R_*}\text{‘}x,$$

whence

$*97{\cdot}21$. $\vdash : R \in 1 \to 1 \,.\supset .\, \overleftrightarrow{R_*}\text{“}s\text{‘gen‘}R = \overleftarrow{R_*}\text{“}\overrightarrow{B}\text{‘}R$

When $R \in 1 \to 1$, the relation of gen‘R to $\overleftarrow{R_*}\text{“}\overrightarrow{B}\text{‘}R$ may be pictured as the relation of rows to columns. *E.g.* let the field of R consist of the dots



in the accompanying rectangle, and let each dot have the relation R to the dot below it. Then the top row is $\overrightarrow{B}\text{‘}R$, the second row is $\text{Ɑ‘}R - \text{Ɑ‘}R^2$, the third is $\text{Ɑ‘}R^2 - \text{Ɑ‘}R^3$, and so on; thus the rows are the generations of R. Again, if x is any dot in the top row, the column beginning with x is $\overleftarrow{R_*}\text{‘}x$, and if y is any member of this column, the column is $\overleftrightarrow{R_*}\text{‘}y$. Thus the columns are the families of R. It will be seen that in the case represented by the above figure, every family consists of a selection from the generations, and every generation consists of a selection from the families, *i.e.*

$$\overleftarrow{R_*}\text{“}\overrightarrow{B}\text{‘}R \subset \text{D“}\epsilon_\Delta\text{‘gen‘}R \,.\, \text{gen‘}R \subset \text{D“}\epsilon_\Delta\text{‘}\overleftarrow{R_*}\text{“}\overrightarrow{B}\text{‘}R.$$

The circumstances under which this occurs will be considered in the present number (∗97·3—·47). The results are summed up in ∗97·47.

The remaining propositions (∗97·5—·58) are concerned with *circular* families of one-one relations. If $R \epsilon 1 \to 1$, $\overleftrightarrow{R}_*‘x$ is a circular family if $xR_{\mathrm{po}}x$. In that case, we have $xR_{\mathrm{po}}y \,.\supset.\, yR_{\mathrm{po}}x$; moreover there is a definite power of R, say P, such that every member of the family of x has the relation P to itself (∗97·54). (The same will hold, of course, of all powers of P.) The families of a $1 \to 1$ are all either circular or open, *i.e.* we have (∗97·55) either $y \epsilon \overleftrightarrow{R}_*‘x \,.\supset_y.\, yR_{\mathrm{po}}y$, or $y \epsilon \overleftrightarrow{R}_*‘x \,.\supset_y.\, \sim(yR_{\mathrm{po}}y)$. The Q-shaped families considered in ∗96 are not possible for a $1 \to 1$, since in such families the term at the junction of the tail and the circle has two predecessors. The family of any member of $s‘\mathrm{gen}‘R$ must be open (∗97·57). The family of a member of $p‘\text{Ɑ}‘‘\mathrm{Pot}‘R$ need not be closed, but cannot have a beginning; if open, it forms a series of type $^*\omega$ or $^*\omega + \omega$, according as it has or has not an end*. Finite open families are contained in $s‘\mathrm{gen}‘R \cap s‘\mathrm{gen}‘\breve{R}$; families of type ω are contained in $s‘\mathrm{gen}‘R \cap p‘\text{Ɑ}‘‘\mathrm{Pot}‘\breve{R}$; those of type $^*\omega$, in $s‘\mathrm{gen}‘\breve{R} \cap p‘\text{Ɑ}‘‘\mathrm{Pot}‘R$; those of type $^*\omega + \omega$ and circular families are contained in $p‘\text{Ɑ}‘‘\mathrm{Pot}‘R \cap p‘\text{Ɑ}‘‘\mathrm{Pot}‘\breve{R}$. Those of type $^*\omega + \omega$ are distinguished from circular families by the fact that in the former we do not have $xR_{\mathrm{po}}x$, while in the latter we do have this.

In addition to the propositions already mentioned, the most useful propositions of the present number are the following:

∗97·13. $\vdash .\, \overleftrightarrow{R}_*‘x = \overrightarrow{R}_*‘x \cup \overleftarrow{R}_*‘x$

∗97·17. $\vdash .\, \overleftrightarrow{R}_*‘x = \overleftrightarrow{R}_{\mathrm{po}}‘x = \overrightarrow{R}_*‘x \cup \overleftarrow{R}_{\mathrm{po}}‘x = \overrightarrow{R}_{\mathrm{po}}‘x \cup \overleftarrow{R}_*‘x$

∗97·5. $\vdash : R \epsilon \mathrm{Cls} \to 1 \,.\, xR_{\mathrm{po}}x \,.\, xR_{\mathrm{po}}y \,.\supset.\, yR_{\mathrm{po}}x$

∗97·501. $\vdash : R \epsilon 1 \to \mathrm{Cls} \,.\, xR_{\mathrm{po}}x \,.\, yR_{\mathrm{po}}x \,.\supset.\, xR_{\mathrm{po}}y$

∗97·01. $\overleftrightarrow{R}‘x = \overrightarrow{R}‘x \cup (\iota‘x \cap C‘R) \cup \overleftarrow{R}‘x$ Df

Observe that "$\iota‘x \cap C‘R$" means that x is to be included if it is a member of $C‘R$, but not otherwise; for $\iota‘x \cap C‘R = \iota‘x$ if $x \epsilon C‘R$, and otherwise $\iota‘x \cap C‘R = \Lambda$.

* Here the type "$^*\omega$" is the type of converses of relations of type ω, *i.e.* the type of the negative integers in order of magnitude, ending with -1, ω being the type of the positive integers in order of magnitude, and therefore $^*\omega+\omega$ being the type of negative and positive integers in order of magnitude.

$\vdash : R \epsilon 1 \rightarrow \text{Cls} . \supset . s`\overleftrightarrow{R_*}``s`\text{gen}`R \subset s`\text{gen}`R .$
$s`\overleftrightarrow{R_*}``p`\text{Ꮖ}``\text{Pot}`R \subset p`\text{Ꮖ}``\text{Pot}`R : \supset \vdash . \text{Prop}$

It follows from this proposition that every family is either wholly contained in the generations of R or wholly contained in $p`\text{Ꮖ}``\text{Pot}`R$, which may be called the *residue* of the field of R.

APPENDIX A

$*8$. THE THEORY OF DEDUCTION FOR PROPOSITIONS CONTAINING APPARENT VARIABLES*

ALL propositions, of whatever order, are derived from a matrix composed of elementary propositions combined by means of the stroke. Given such a matrix, any constituent may be left constant or turned into an apparent variable; the latter may be done in two ways, by taking "all values" or "some values." Thus, if p and q are elementary propositions, giving rise to $p \mid q$, we may replace p by ϕx or q by ψy or both, where ϕx, ψy are propositional functions whose values are elementary propositions. We thus arrive, to begin with, at four new propositions:

$$(x) \,.\, (\phi x \mid q), \quad (\exists x) \,.\, (\phi x \mid q), \quad (y) \,.\, (p \mid \psi y), \quad (\exists y) \,.\, (p \mid \psi y).$$

By means of definitions, we can separate out the constant and the variable part in these expressions; we put

$*8{\cdot}01$. $\{(x) \,.\, \phi x\} \mid q \,. = .\, (\exists x) \,.\, (\phi x \mid q)$ Df

$*8{\cdot}011$. $\{(\exists x) \,.\, \phi x\} \mid q \,. = .\, (x) \,.\, (\phi x \mid q)$ Df

$*8{\cdot}012$. $p \mid \{(y) \,.\, \psi y\} \,. = .\, (\exists y) \,.\, (p \mid \psi y)$ Df

$*8{\cdot}013$. $p \mid \{(\exists y) \,.\, \psi y\} \,. = .\, (y) \,.\, (p \mid \psi y)$ Df

These definitions define the meaning of the stroke when it occurs between two propositions of which one is elementary while the other is of the first order.

When the stroke occurs between two propositions which are both of the first order, we shall adopt the rule that the above definitions are to be applied first to the one on the left, treating the one on the right as if it were elementary, and are then to be applied to the one on the right. Thus

$$\begin{aligned} \{(x) \,.\, \phi x\} \mid \{(y) \,.\, \psi y\} \,. &= : (\exists x) : \phi x \mid \{(y) \,.\, \psi y\} : \\ &= : (\exists x) : (\exists y) \,.\, (\phi x \mid \psi y). \end{aligned}$$

The same rule can be applied to n propositions; they are to be eliminated from left to right. If a proposition occurs more than once, its occurrences must be eliminated successively as if they were different propositions. These rules are only required for the sake of definiteness, as different orders of elimination give equivalent results. This is only true because we are dealing with various functions each containing one variable, and no variable occurs on both sides of the stroke; it would not be true if we were dealing with functions of several variables. We have *e.g.*

$$(\exists x) : (y) \,.\, (\phi x \mid \psi y) : \equiv : (y) : (\exists x) \,.\, (\phi x \mid \psi y).$$

* This chapter is to replace $*9$ of the text.

But we do not have in general

$$(\exists x):(y).\chi(x,y):\equiv:(y):(\exists x).\chi(x,y);$$

here the right-hand side is more likely to be true than the left-hand side. For the present, however, we are not concerned with variable functions of two variables.

It should be observed that this possibility of changing the order of the variables is a merit of the stroke. We have

$$(\exists x):(y).\phi x|\psi y:\equiv:(y):(\exists x).\phi x|\psi y:\equiv:(\exists x).\sim\phi x.\vee.(y).\sim\psi y.$$

That is, these equivalent propositions are true when, and only when, either ϕ is sometimes false or ψ is always false. But if we take *e.g.*

$$\phi x \vee \psi y . \sim\phi x \vee \sim\psi y$$

we shall not get the same result. For

$$(\exists x):(y).\phi x \vee \psi y . \sim\phi x \vee \sim\psi y:\supset:(y).\psi y.\vee.(y).\sim\psi y,$$

whereas $(y):(\exists x).\phi x \vee \psi y . \sim\phi x \vee \sim\psi y$ does not imply this.

Written in stroke notation, after some reduction, the above matrix is

$$\{\phi x|(\psi y|\psi y)\}|\{\psi y|(\phi x|\phi x)\}.$$

Here both x and y occur on both sides of the principal matrix. Thus in order to be able to change the order of "$(\exists x)$" and "(y)," it is sufficient (though not *always* necessary) that the matrix should contain some part of the form $\phi x|\psi y$, and that x and y should not occur in any other part of the matrix. (This part may of course be the whole matrix.) We assume the legitimacy of this interchange by a primitive proposition, and in practice arrange to have all the $\exists$-prefixes as far to the right as possible, because this facilitates proofs.

Our primitive propositions are the following:

***8·1.** $\vdash.(\exists x,y).\phi a|(\phi x|\phi y)$ Pp

On applying the definitions, this is seen to be

$$\vdash:\phi a.\supset.(\exists x).\phi x.$$

***8·11.** $\vdash.(\exists x).\phi x|(\phi a|\phi b)$ Pp

On applying the definitions, this becomes

$$\vdash:(x).\phi x.\supset.\phi a.\phi b.$$

We have $\qquad \phi a|(\phi a|\phi b).\vee.\phi b|(\phi a|\phi b)$

and by *8·1 $\qquad \vdash:\phi a|(\phi a|\phi b).\supset.(\exists x).\phi x|(\phi a|\phi b):$

$\qquad \phi b|(\phi a|\phi b).\supset.(\exists x).\phi x|(\phi a|\phi b),$

but we cannot deduce $(\exists x).\phi x|(\phi a|\phi b)$ without *8·11 or an equivalent.

***8·12.** From "$(x).\phi x$" and "$(x).\phi x\supset\psi x$" we can infer "$(x).\psi x$," even when ϕ and ψ are not elementary. Pp

***8·13.** If all occurrences of x are separated from all occurrences of y by a certain stroke, we can change the order of x and y in the prefix, *i.e.* we can replace "$(y):(\exists x).\phi x|\psi y$" by "$(\exists x):(y).\phi x|\psi y$" and *vice versa*. Pp

The above primitive propositions are to be assumed, not only for one or two variables, but for any number. Thus *e.g.* *8·1 allows us to assert

$$\vdash : \phi(a_1, a_2, \ldots a_n) \,.\supset.\, (\exists x_1, x_2, \ldots x_n) \,.\, \phi(x_1, x_2, \ldots x_n).$$

***8·2.** $\vdash : (x) \,.\, \phi x \,.\supset.\, \phi a \quad \left[*8{\cdot}11 \frac{a}{b}\right]$

In what follows, the method of proof is invariably the same. We first apply the definitions until the whole asserted proposition is brought into the form of a matrix with a prefix. If necessary, we apply *8·13 to change the order of the variables in the prefix. When the proposition to be proved has been brought into this form, we deduce it by means of *8·1·11, using *8·12 in the deduction if necessary. It will be observed that *8·1 is $\vdash : \phi a \,.\supset.\, (\exists x) \,.\, \phi x$. Hence, by *8·12, whenever we know ϕa, we can assert $(\exists x) \,.\, \phi x$; *8·1 is often used in this way.

***8·21.** $\vdash :. (x) \,.\, \phi x \supset \psi x \,.\supset : (\exists x) \,.\, \phi x \,.\supset.\, (\exists x) \,.\, \psi x$

Dem.

Applying the definitions, and using *8·13, the proposition to be proved becomes

$$(y, y') : (\exists x, z, w, z', w') \,.\, \{\phi x \mid (\psi x \mid \psi x)\} \mid [\{\phi y \mid (\psi z \mid \psi w)\} \mid \{\phi y' \mid (\psi z' \mid \psi w')\}].$$

Putting $z = w = z' = w' = x$, the above becomes

$$(y, y') : (\exists x) \,.\, \{\phi x \mid (\psi x \mid \psi x)\} \mid [\{\phi y \mid (\psi x \mid \psi x)\} \mid \{\phi y' \mid (\psi x \mid \psi x)\}].$$

By *8·1, the proposition to be proved is true if this is true. But this is true by *8·11, putting y, y' for a, b and $\phi y \mid (\psi x \mid \psi x)$ for ϕa. Hence the proposition is true.

***8·22.** $\vdash : \phi a \vee \phi b \,.\supset.\, (\exists x) \,.\, \phi x$

Dem.

$\vdash \,.\, *8{\cdot}11 \,.\supset \vdash \,.\, (\exists z) \,.\, (\sim \phi z) \mid (\sim \phi a \mid \sim \phi b)$		(1)
Transp.	$\supset \vdash : (\sim \phi z) \mid (\sim \phi a \mid \sim \phi b) \,.\supset.\, (\phi a \vee \phi b) \mid (\phi z \mid \phi z)$	(2)
$\vdash \,.\, (1) \,.\, (2) \,.\, *8{\cdot}21 \,.\supset \vdash \,.\, (\exists z) \,.\, (\phi a \vee \phi b) \mid (\phi z \mid \phi z)$		(3)
$\vdash \,.\, (3) \,.\, *8{\cdot}1{\cdot}21 \,.$	$\supset \vdash \,.\, (\exists z, w) \,.\, (\phi a \vee \phi b) \mid (\phi z \mid \phi w) \,.$	
[(*8·012·013)]	$\supset \vdash : \phi a \vee \phi b \,.\supset.\, (\exists x) \,.\, \phi x : \supset \vdash .$ Prop	

These propositions, as well as all the others in *8, apply to any number of variables, since the primitive propositions do so.

***8·23.** $\vdash : (\exists x) \,.\, \phi x \vee \phi c \,.\supset.\, (\exists x) \,.\, \phi x$

Dem.

Applying the definitions, this proposition is

$$(x) : (\exists y, z) \,.\, (\phi x \vee \phi c) \mid (\phi y \mid \phi z),$$

i.e.

$$(x) : \phi x \vee \phi c \,.\supset.\, (\exists x) \,.\, \phi x,$$

which follows from *8·22.

The following propositions are concerned with forms of the syllogism.

***8·24.** $\vdash :: p \supset q . \supset :. q . \supset . (\exists x) . \phi x : \supset : p . \supset . (\exists x) . \phi x$

Dem.

Applying the definitions, we obtain a matrix

$(p \supset q) \mid [\{(q \mid (\phi x \mid \phi y)) \mid (p \mid (\phi z \mid \phi w) \mid p \mid (\phi u \mid \phi v))\} \mid$ {the same with accented letters}]

with a prefix

$$(x, y, x', y') : (\exists z, w, u, v, z', w', u', v').$$

By *8·1, this will be true if it is true for chosen values of $z, w, u, v, z', w', u', v'$. Put $z = u = x . w = v = y . z' = u' = x' . w' = v' = y'$. Then what has to be proved becomes

$p \supset q . \supset :. q . \supset . \phi x . \phi y : \supset : p . \supset . \phi x . \phi y :. q . \supset . \phi x' . \phi y' : \supset : p . \supset . \phi x' . \phi y'$,

which is true by Syll. Hence the proposition follows.

***8·241.** $\vdash :: (x) . \phi x . \supset . p : \supset :. p \supset q . \supset : (x) . \phi x . \supset . q$

Putting $f(y, z) . = . \{p \mid (q \mid q)\} \mid [\{\phi y \mid (q \mid q)\} \mid \{\phi z \mid (q \mid q)\}]$,

the matrix of the proposition to be proved is

$$\{\phi x \mid (p \mid p)\} \mid \{f(y, z) \mid f(y', z')\}$$

and the prefix is $(x) : (\exists y, z, y', z')$. Putting $y = z = y' = z' = x$, the matrix reduces to $\phi x \supset p . \supset : p \supset q . \supset . \phi x \supset q$, which is true by Syll. Hence the proposition is true by *8·1.

***8·25.** $\vdash :: p . \supset . (\exists x) . \phi x : \supset :. (\exists x) . \phi x . \supset . (\exists x) . \psi x : \supset : p . \supset . (\exists x) . \psi x$

Dem.

Put $f(x, y, z, u, v, m, n) . = . \{\phi x \mid (\psi y \mid \psi z)\} \mid [\{p \mid (\psi u \mid \psi v)\} \mid \{p \mid (\psi m \mid \psi n)\}]$. Then the proposition to be proved, on applying the definitions, is found to have a matrix

$$\{p \mid (\phi a \mid \phi b)\} \mid \{f(x, y, z, u, v, m, n) \mid f(x', y', z', u', v', m', n')\}$$

with the prefix

$$(a, b, y, z, y', z') : (\exists x, u, v, m, n, x', u', v', m', n').$$

Put $x = a . x' = b . u = v = y . m = n = z . u' = v' = y' . m' = n' = z'$.

Then the matrix reduces to

$$p . \supset . \phi a . \phi b : \supset :. \phi a . \supset . \psi y . \psi z : \supset : p . \supset . \psi y . \psi z :.$$
$$\phi b . \supset . \psi y' . \psi z' : \supset : p . \supset . \psi y' . \psi z',$$

which is true by Syll. Hence our proposition results by repeated applications of *8·1·13.

Analogous proofs apply to other forms of the syllogism.

***8·26.** $\vdash : \phi a \vee \phi b \vee \phi c . \supset . (\exists x) . \phi x \vee \phi c$

Dem.

$\vdash : \phi a \vee \phi b \vee \phi c . \supset . (\phi a \vee \phi c) \vee (\phi b \vee \phi c)$ (1)

$\vdash . *8·22 . \supset \vdash : (\phi a \vee \phi c) \vee (\phi b \vee \phi c) . \supset . (\exists x) . \phi x \vee \phi c$ (2)

$\vdash . (1) . (2) . *8·24 . \supset \vdash . \text{Prop}$

***8·261.** $\vdash : \phi a \vee \phi b \vee \phi c \,.\supset.\, (\exists x) \,.\, \phi x$
[*8·25·26·23]

It is obvious that we can prove in like manner

$$\phi a \vee \phi b \vee \phi c \vee \phi d \,.\supset.\, (\exists x) \,.\, \phi x$$

and so on.

***8·27.** $\vdash :: q \,.\supset.\, (\exists x) \,.\, \phi x : \supset :. p \supset q \,.\supset : p \,.\supset.\, (\exists x) \,.\, \phi x$

Dem.

Put $\quad f(x, y, u, v) \,.=.\, \{p \mid (\phi x \mid \phi y)\} \mid \{p \mid (\phi u \mid \phi v)\}.$

Then the matrix is

$$\{q \mid (\phi a \mid \phi b)\} \mid [\{(p \supset q) \mid f(x, y, u, v)\} \mid \{(p \supset q) \mid f(x', y', u', v')\}]$$

and the prefix is $\quad (a, b) : (\exists x, y, u, v, x', y', u', v').$

Putting $x = u = x' = u' = a \,.\, y = v = y' = v' = b$, the matrix becomes

$$q \,.\supset.\, \phi a \,.\, \phi b : \supset :. p \supset q \,.\supset : p \,.\supset.\, \phi a \,.\, \phi b,$$

which is true. Hence the proposition.

***8·271.** $\vdash :: q \,.\supset.\, (\exists x, y) \,.\, \phi(x, y) : \supset :. p \supset q \,.\supset : p \,.\supset.\, (\exists x, y) \,.\, \phi(x, y)$
[Proof as in *8·27]

It is obvious that we can prove similarly the analogous proposition with $\phi(x_1, x_2, \ldots x_n)$ in place of $\phi(x, y)$.

***8·272.** $\vdash ::. p \,.\supset : q \,.\supset.\, (\exists x) \,.\, \phi x :. \supset :: r \supset p \,.\supset :. r \,.\supset : q \,.\supset.\, (\exists x) \,.\, \phi x$

Dem.

$q \,.\supset.\, (\exists x) \,.\, \phi x$ is $(\exists x, y) \,.\, q \mid (\phi x \mid \phi y)$. Hence the proposition results from *8·271 by the substitution of p for q, r for p, and $q \mid (\phi x \mid \phi y)$ for $\phi(x, y)$.

***8·28.** $\vdash :: p \,.\supset.\, (\exists x) \,.\, \phi x : \supset :. q \,.\supset.\, (\exists x) \,.\, \phi x : \supset : p \vee q \,.\supset.\, (\exists x) \,.\, \phi x$

Dem.

Put $\quad f(x, y, z, w) \,.=.\, \{(p \vee q) \mid (\phi x \mid \phi y)\} \mid \{(p \vee q) \mid (\phi z \mid \phi w)\}.$

Then the matrix is

$$\{p \mid (\phi a \mid \phi b)\} \mid [\{(q \mid (\phi c \mid \phi d)) \mid f(x, y, z, w)\} \mid \{(q \mid (\phi c' \mid \phi d')) \mid f(x', y', z', w')\}]$$

and the prefix is

$$(a, b, c, d, c', d') : (\exists x, y, z, w, x', y', z', w').$$

The matrix is

$$p \,.\supset.\, \phi a \,.\, \phi b : \supset :. q \,.\supset.\, \phi c \,.\, \phi d : \supset . f(x, y, z, w) :.$$
$$q \,.\supset.\, \phi c' \,.\, \phi d' \,.\supset . f(x', y', z', w'),$$

while $\quad f(x, y, z, w) \,.\equiv : p \vee q \,.\supset.\, \phi x \,.\, \phi y \,.\, \phi z \,.\, \phi w.$

Call the matrix $\quad F(x, y, z, w, x', y', z', w').$

Then $\quad \vdash : p \,.\supset.\, F(a, b, a, b, a, b, a, b),$

$\quad \vdash : \sim p \,.\supset.\, F(c, d, c, d, c', d', c', d').$

Hence $\quad \vdash : F(a, b, a, b, a, b, a, b) \,.\vee.\, F(c, d, c, d, c', d', c', d').$

Hence, by the extension of $*8{\cdot}261$ to eight variables,

$$\vdash . (\exists x, y, z, w, x', y', z', w') . F(x, y, z, w, x', y', z', w'),$$

which was to be proved.

$*8{\cdot}29$. $\vdash :. (x) . \phi x \supset \psi x . \supset : (x) . \phi x . \supset . (x) . \psi x$

Dem.

Applying the definitions, our proposition is found to have a matrix

$$(\phi x \supset \psi x) \mid [\{\phi y \mid (\psi u \mid \psi v)\} \mid \{\phi y' \mid (\psi u' \mid \psi v')\}]$$

with a prefix (after using $*8{\cdot}13$)

$$(u, v, u', v') : (\exists x, y, y').$$

The matrix is equivalent to

$$\phi x \supset \psi x . \supset : \phi y . \supset . \psi u . \psi v : \phi y' . \supset . \psi u' . \psi v'.$$

Calling this $M(x, y, y')$, we have to prove

$$(\exists x, y, y') . M(x, y, y').$$

If $\psi u . \psi v . \psi u' . \psi v'$, $M(x, y, y')$ is always true. (1)

If $\sim \psi u$, put $x = y = y' = u$. Then if ϕu is true, $\phi u \supset \psi u$ is false and $M(u, u, u)$ is true. But if ϕu is false, $\phi u . \supset . \psi u . \psi v$ and $\phi u . \supset . \psi u' . \psi v'$ are true, so that $M(u, u, u)$ is true. Hence

$$\sim \psi u . \supset . M(u, u, u) . \supset . (\exists x, y, y') . M(x, y, y'). \quad (2)$$

Similarly if $\qquad \sim \psi v \vee \sim \psi u' \vee \sim \psi v'.$ (3)

(1), (2), and (3) exhaust possible cases. Hence the result by $*8{\cdot}28$.

We are now in a position to prove that all the propositions of $*1$—$*5$ remain true when one or more of the propositions $p, q, r, \ldots$ are first-order propositions instead of being elementary propositions. For this purpose, we take, not the one primitive proposition which Nicod has shown to be sufficient, but the two which he has shown to be equivalent to it, namely:

$$p \supset p \text{ and } p \supset q . \supset . s \mid q \supset p \mid s.$$

We show that these are true when one, or two, or three, of the propositions p, q, s are first-order propositions. From this, the rest follows. The first of these primitive propositions, $p \supset p$, gives rise to two cases, according as we substitute $(x) . \phi x$ or $(\exists x) . \phi x$ for p; the second primitive proposition gives rise to 26 cases. These have to be considered one by one.

$*8{\cdot}3$. $\vdash : (x) . \phi x . \supset . (x) . \phi x$

Applying the definitions, this is $(\exists x) : (y, z) . \phi x \mid (\phi y \mid \phi z)$, which follows from $*8{\cdot}11$ by $*8{\cdot}13$.

$*8{\cdot}31$. $\vdash : (\exists x) . \phi x . \supset . (\exists x) . \phi x$

Applying the definitions, this is $(x) : (\exists y, z) . \phi x \mid (\phi y \mid \phi z)$. This is $*8{\cdot}1$.

This completes the proof of $p \supset p$.

∗8·32. $\vdash :. (x) . \phi x . \supset . q : \supset : s \mid q . \supset . \{(x) . \phi x\} \mid s$

Putting $p . = . (x) . \phi x$, the proposition to be proved is

$$(p \mid \sim q) \mid \sim \{(s \mid q) \mid \sim (p \mid s)\}.$$

By the definitions,

$$p \mid \sim q . = . (\exists a) . \phi a \mid (q \mid q), \qquad (1)$$

$$p \mid s . = . (\exists x) . \phi x \mid s,$$

$$\sim (p \mid s) . = . (x, y) . (\phi x \mid s) \mid (\phi y \mid s),$$

$$(s \mid q) \mid \sim (p \mid s) . = . (\exists x, y) . (s \mid q) \mid \{(\phi x \mid s) \mid (\phi y \mid s)\}.$$

Put $\qquad f(x, y) . = . (s \mid q) \mid \{(\phi x \mid s) \mid (\phi y \mid s)\}.$

Then $\qquad \sim \{(s \mid q) \mid \sim (p \mid s)\} . = . (x, y, x', y') . f(x, y) \mid f(x', y'). \qquad (2)$

By (1) and (2), the proposition to be proved is

$$(a) : (\exists x, y, x', y') . \{\phi a \mid (q \mid q)\} \mid \{f(x, y) \mid f(x', y')\}.$$

Putting $x = y = x' = y' = a$, the matrix of this proposition reduces to

$$\phi a \supset q . \supset . s \mid q \supset \phi a \mid s,$$

which is our primitive proposition with ϕa substituted for p, and is therefore true. Hence the proposition follows by ∗8·1.

In what follows, the reduction of the proposition to be proved to a matrix and prefix, by means of the definitions, proceeds always by the same method, and the steps will usually be omitted.

∗8·321. $\vdash :. (\exists x) . \phi x . \supset . q : \supset : s \mid q . \supset . \{(\exists x) . \phi x\} \mid s$

We obtain the same matrix as in ∗8·32, but the opposite prefix, *i.e.* the prefix is

$$(x, y, x', y') : (\exists a).$$

The matrix is equivalent to

$$\phi a \supset q . \supset : q \supset \sim s . \supset . \phi x \supset \sim s . \phi y \supset \sim s . \phi x' \supset \sim s . \phi y' \supset \sim s.$$

Calling this fa, we have to prove $(\exists a) . fa$, for any x, y, x', y'. We have

$$\phi a . \sim q . \supset . fa.$$

Also $\phi a . q . \supset :. fa . \equiv : \sim s . \supset . \phi x \supset \sim s . \phi y \supset \sim s . \phi x' \supset \sim s . \phi y' \supset \sim s :.$
$\qquad \supset :. fa.$

Hence $\qquad \phi a . \supset . fa.$

Hence by ∗8·1·24 $\qquad \phi x . \supset . (\exists a) . fa,$

and similarly for ϕy, $\phi x'$, $\phi y'$. Hence by ∗8·261

$$\phi x \vee \phi y \vee \phi x' \vee \phi y' . \supset . (\exists a) . fa.$$

Also $\qquad \sim \phi x . \sim \phi y . \sim \phi x' . \sim \phi y' . \supset . fa .$

$\qquad$ [∗8·1·24] $\qquad \supset . (\exists a) . fa.$

Hence by ∗8·28

$$\phi x \vee \phi y \vee \phi x' \vee \phi y' \vee \sim \phi x . \sim \phi y . \sim \phi x' . \sim \phi y' : \supset . (\exists a) . fa.$$

Hence, by ∗8·12, $(\exists a) . fa$, which was to be proved.

***8·322.** $\vdash :. p . \supset . (x) . \psi x : \supset : s \mid \{(x) . \psi x\} . \supset . p \mid s$

Dem.

Put $$fy . = . (s \mid \psi y) \mid \{(p \mid s) \mid (p \mid s)\}.$$

Then the proposition to be proved is

$$(y, y') : (\exists b, c) . \{p \mid (\psi b \mid \psi c)\} \mid (fy \mid fy').$$

The matrix here is equivalent to

$$p . \supset . \psi b . \psi c : \supset : s \mid \psi y . \supset . p \mid s : s \mid \psi y' . \supset . p \mid s.$$

Putting $b = y . c = y'$, this follows at once from the primitive proposition, which gives

$$p \supset \psi y . \supset : s \mid \psi y . \supset . p \mid s,$$
$$p \supset \psi y' . \supset : s \mid \psi y' . \supset . p \mid s.$$

Hence the proposition.

***8·323.** $\vdash :. p . \supset . (\exists x) . \psi x : \supset : s \mid \{(\exists x) . \psi x\} . \supset . p \mid s$

We have the same matrix as in *8·322, but the opposite prefix, *i.e.*

$$(b, c) : (\exists y, y').$$

Putting $y = b . y' = c$, the matrix is satisfied, as in *8·322.

***8·324.** $\vdash :. p \supset q . \supset : \{(x) . \chi x\} \mid q . \supset . p \mid \{(x) . \chi x\}$

Dem.

Put $f(x, y, z) . = . (\chi x \mid q) \mid \{(p \mid \chi y) \mid (p \mid \chi z)\}$. Then the matrix is

$$\{p \mid (q \mid q)\} \mid \{f(x, y, z) \mid f(x', y', z')\}$$

and the prefix is $(x, x') : (\exists y, z, y', z')$. Putting

$$y = z = x . y' = z' = x',$$

the matrix is equivalent to

$$p \supset q . \supset : \chi x \mid q . \supset . p \mid \chi x : \chi x' \mid q . \supset . p \mid \chi x',$$

which follows from our primitive proposition by Comp.

***8·325.** $\vdash :. p \supset q . \supset : \{(\exists x) . \chi x\} \mid q . \supset . p \mid \{(\exists x) . \chi x\}$

Dem.

The matrix is the same as in *8·324, but the prefix is the opposite, *i.e.*

$$(y, z, y', z') : (\exists x, x').$$

Calling the matrix $M(x, x')$, we have, if $\theta w . \equiv_w . \sim \chi w$,

$$M(x, x') . \equiv :: p \supset q . \supset :. q \supset \theta x . \supset : p . \supset . \theta y . \theta z :. q \supset \theta x' . \supset : p . \supset . \theta y' . \theta z'.$$

Hence $$\theta y . \theta z . \theta y' . \theta z' . \supset . M(x, x') . \supset . (\exists x, x') . M(x, x') \quad (1)$$

But $\sim \theta x . \sim \theta x' . \supset . M(x, x')$. Hence

$$\sim \theta x . \supset . M(x, x) . \supset . (\exists x, x') . M(x, x') \quad (2)$$

Similarly with $\theta y, \theta x', \theta y'$. Hence the result follows as in *8·321.

This ends the cases in which only one of p, q, r in

$$p \supset q . \supset : s \mid q . \supset . p \mid s$$

is of the first order instead of being elementary. We have now to deal with the cases in which two, but not three, are of the first order.

***8·33.** $\vdash :. (x) . \phi x . \supset . (x) . \psi x : \supset : s \mid \{(x) . \psi x\} . \supset . \{(x) . \phi x\} \mid s$

Putting $f(x, y, z) . = . (s \mid \psi x) \mid \{(\phi y \mid s) \mid (\phi z \mid s)\}$, the matrix is

$$\{\phi a \mid (\psi b \mid \psi c)\} \mid \{f(x, y, z) \mid f(x', y', z')\}$$

and the prefix is $(a, x, x') : (\exists b, c, y, z, y', z')$. The matrix is satisfied by

$$b = x . c = x' . y = z = y' = z' = a,$$

in which case it is equivalent to

$$\phi a . \supset . \psi x . \psi x' : \supset :. \psi x \supset \sim s . \supset . \phi a \supset \sim s : \psi x' \supset \sim s . \supset . \phi a \supset \sim s.$$

Hence Prop.

We have the same matrix in the three following propositions, only with different prefixes.

***8·331.** $\vdash :. (x) . \phi x . \supset . (\exists x) . \psi x : \supset : s \mid \{(\exists x) . \psi x\} . \supset . \{(x) . \phi x\} \mid s$

Here the prefix to the matrix is $(a, b, c) : (\exists x, y, z, x', y', z')$. The matrix is satisfied by $x = b . x' = c . y = z = y' = z' = a$. Hence Prop.

***8·332.** $\vdash :. (\exists x) . \phi x . \supset . (x) . \psi x : \supset : s \mid \{(x) . \psi x\} . \supset . \{(\exists x) . \phi x\} \mid s$

The prefix here is $(x, y, z, x', y', z') : (\exists a, b, c)$. Writing r for $\sim s$, matrix becomes

$$\phi a . \supset . \psi b . \psi c : \supset :. \psi x \supset r . \supset . \phi y \vee \phi z \supset r : \psi x' \supset r . \supset . \phi y' \vee \phi z' \supset r.$$

(Here only a, b, c can be chosen arbitrarily.) This is true if $\phi y, \phi z, \phi y', \phi z'$ are all false. Suppose ϕy is true. Put $a = y$. Then if ψb or ψc is false, $\phi a . \supset . \psi b . \psi c$ is false, and the matrix is true. Therefore if ψx is false, put $b = c = x$; if $\psi x'$ is false, put $b = c = x'$. If ψx and $\psi x'$ are both true, putting $a = y . b = c = x$, the matrix becomes equivalent to

$$r . \supset . \phi y \vee \phi z \supset r : r . \supset . \phi y' \vee \phi z' \supset r,$$

which is true. Hence if ϕy is true, the matrix can be made true. Similarly for z, y', z'. This exhausts possible cases. Hence Prop, by *8·28.

***8·333.** $\vdash :. (\exists x) . \phi x . \supset . (\exists x) . \psi x : \supset : s \mid \{(\exists x) . \psi x\} . \supset . \{(\exists x) . \phi x\} \mid s$

Dem.

The matrix is as before, and the prefix (after using *8·13) is

$$(b, c, y, z, y', z') : (\exists a, x, x').$$

Call the matrix $M(a, x, x')$. Then

$\vdash : \psi b . \supset . M(a, b, b) . \supset . (\exists a, x, x') . M(a, x, x')$ (1)

$\vdash : \psi c . \supset . M(a, c, c) . \supset . (\exists a, x, x') . M(a, x, x')$ (2)

$\vdash : \sim \psi b . \sim \psi c . \phi y . \supset . M(y, b, c) . \supset . (\exists a, x, x') . M(a, x, x')$ (3)

$(1) . (2) . (3) . \supset \vdash : \phi y . \supset . (\exists a, x, x') . M(a, x, x')$ [using *8·28] (4)

Similarly for $\phi y', \phi z, \phi z'$. Hence by *8·28

$\vdash : \phi y \vee \phi y' \vee \phi z \vee \phi z' . \supset . (\exists a, x, x') . M(a, x, x')$ (5)

But $\vdash :. \sim \phi y . \sim \phi y' . \sim \phi z . \sim \phi z' . \supset : \phi y \vee \phi z \supset r . \phi y' \vee \phi z' \supset r :$

$\supset : M(a, x, x')$

[*8·1] $\supset : (\exists a, x, x') . M(a, x, x')$ (6)

$\vdash . (5) . (6) . *8·28 . \supset \vdash . (\exists a, x, x') . M(a, x, x') . \supset \vdash . \text{Prop}$

This ends the cases in which p and q but not s contain apparent variables. We take next the four cases in which p and s, but not q, contain apparent variables.

***8·34.** $\vdash :. (x) . \phi x . \supset . q : \supset : \{(x) . \chi x\} \mid q . \supset . \{(x) . \phi x\} \mid \{(x) . \chi x\}$

Putting $f(x, y, z, u, v) . = . (\chi x \mid q) \mid \{(\phi y \mid \chi z) \mid (\phi u \mid \chi v)\}$, the matrix is

$$(\phi a \mid \sim q) \mid \{f(x, y, z, u, v) \mid f(x', y', z', u', v')\}.$$

(This is also the matrix of the three following propositions.)

The prefix is $(a, x, x') : (\exists y, z, u, v, y', z', u', v')$.

The matrix is equivalent to

$$\phi a \supset q . \supset . f(x, y, z, u, v) . f(x', y', z', u', v')$$

and $\qquad f(x, y, z, u, v) . \equiv : \chi x \mid q . \supset . \phi y \mid \chi z . \phi u \mid \chi v :$

$$\equiv : q \supset \sim \chi x . \supset . \phi y \supset \sim \chi z . \phi u \supset \sim \chi v.$$

Putting $y = u = y' = u' = a . z = v = x . z' = v' = x'$, the matrix is satisfied. Hence Prop.

***8·341.** $\vdash :. (x) . \phi x . \supset . q : \supset : \{(\exists x) . \chi x\} \mid q . \supset . \{(x) . \phi x\} \mid \{(\exists x) . \chi x\}$

Matrix as in *8·34. Prefix $(a, z, v, z', v') : (\exists x, y, u, x', y', u')$.

Matrix is equivalent to

$$\phi a \supset q . \supset :. q \supset \sim \chi x . \supset . \phi y \supset \sim \chi z . \phi u \supset \sim \chi v :$$
$$q \supset \sim \chi x' . \supset . \phi y' \supset \sim \chi z' . \phi u' \supset \sim \chi v'.$$

If ϕa is false, this becomes true by putting $y = u = y' = u' = a$. If ϕa is true, the matrix is true if q is false. Suppose q true. Then the matrix is equivalent to

$$\sim \chi x . \supset . \phi y \supset \sim \chi z . \phi u \supset \sim \chi v : \sim \chi x' . \supset . \phi y' \supset \sim \chi z' . \phi u' \supset \sim \chi v'.$$

This is true if χz, χv, $\chi z'$, $\chi v'$ are false. If one of them, say χz, is true, put $x = x' = z$, and the matrix is true. This exhausts possible cases. Hence Prop, by *8·28.

***8·342.** $\vdash :. (\exists x) . \phi x . \supset . q : \supset : \{(x) . \chi x\} \mid q . \supset . \{(\exists x) . \phi x\} \mid \{(x) . \chi x\}$

Matrix as before. Prefix (after using *8·13) $(x, y, u, x', y', u') : (\exists a, z, v, z', v')$.

Call the matrix $M(a, z, v, z', v')$. Then

$$\vdash : \sim \chi x . \quad \supset . M(a, x, x, x, x) \tag{1}$$
$$\vdash : \sim \chi x' . \quad \supset . M(a, x', x', x', x') \tag{2}$$
$$\vdash : q . \chi x . \chi x' . \supset . \sim(q \supset \sim \chi x) . \sim(q \supset \sim \chi x') .$$
$$\supset . M(a, z, v, z', v') \tag{3}$$
$$\vdash : \sim q . \phi y . \quad \supset . \sim(\phi y \supset q) .$$
$$\supset . M(y, z, v, z', v') \tag{4}$$

Similarly if $\sim q . \phi u$ or $\sim q . \phi y'$ or $\sim q . \phi u'$. Hence by *8·1·28

$$\vdash : \sim q . \phi y \lor \phi u \lor \phi y' \lor \phi u' . \supset . (\exists a, z, v, z', v') . M(a, z, v, z', v') \tag{5}$$
$$\vdash : \sim \phi y . \sim \phi u . \sim \phi y' . \sim \phi u' . \supset . \phi y \supset \sim \chi z . \phi u \supset \sim \chi v . \phi y' \supset \sim \chi z' . \phi u' \supset \sim \chi v'$$
$$\supset . M(a, z, v, z', v') \tag{6}$$
$$(5) . (6) . \supset \vdash : \sim q . \quad \supset . (\exists a, z, v, z', v') . M(a, z, v, z', v') \tag{7}$$

$\vdash . (1) . (2) . (3) . (7) . \supset \vdash .$ Prop

$*8{\cdot}343.\ \vdash :. (\exists x) . \phi x . \supset . q : \supset : \{(\exists x) . \chi x\} \mid q . \supset . \{(\exists x) . \phi x\} \mid \{(\exists x) . \chi x\}$

Prefix to matrix is $(y, z, u, v, y', z', u', v') : (\exists a, x, x')$.

Call the matrix $f(a, x, x')$.

It is true if $\sim\chi z . \sim\chi v . \sim\chi z' . \sim\chi v'$ (1)

Also $\chi z . q . \supset . f(a, z, z) . \supset . (\exists a, x, x') . f(a, x, x')$ (2)

Similarly if we have $\chi v . q$ or $\chi z' . q$ or $\chi v' . q$ (3)

From (1) . (2) . (3), by $*8{\cdot}28$, $q . \supset . (\exists a, x, x') . f(a, x, x')$ (4)

Now $\phi a . \sim q . \supset . f(a, x, x')$. Hence

$$\phi y . \sim q . \supset . f(y, x, x') . \supset . (\exists a, x, x') . f(a, x, x')$$

Similarly for $\phi z . \sim q$, $\phi y' . \sim q$, $\phi z' . \sim q$. Hence

$$\phi y \vee \phi z \vee \phi y' \vee \phi z' . \sim q . \supset . (\exists a, x, x') . f(a, x, x') \quad (5)$$

But $\sim\phi y . \sim\phi z . \sim\phi y' . \sim\phi z' . \supset . f(a, x, x')$ (6)

By (5) and (6), $\sim q . \supset . (\exists a, x, x') . f(a, x, x')$ (7)

$\vdash . (4) . (7) . *8{\cdot}28 . \supset \vdash .$ Prop

In the next four propositions, q and r are replaced by propositions containing apparent variables, while p remains elementary.

$*8{\cdot}35.\ \vdash :. p . \supset . (x) . \psi x : \supset : \{(x) . \chi x\} \mid \{(x) . \psi x\} . \supset . p \mid \{(x) . \chi x\}$

Putting $q . = . (x) . \psi x$, $s . = . (x) . \psi x$, the proposition is

$$(p \mid \sim q) \mid \sim\{(s \mid q) \mid \sim(p \mid s)\}.$$

We have by the definitions

$$\begin{aligned}
\sim q . &= . (\exists b, c) . \psi b \mid \psi c, \\
p \mid \sim q . &= . (b, c) . p \mid (\psi b \mid \psi c), \\
s \mid q . &= . (\exists x, y) . \chi y \mid \psi x, \\
p \mid s . &= . (\exists z) . p \mid \chi z, \\
\sim(p \mid s) . &= . (z, w) . (p \mid \chi z) \mid (p \mid \chi w), \\
(s \mid q) \mid \sim(p \mid s) . &= : (x, y) : (\exists z, w) . (\chi y \mid \psi x) \mid \{(p \mid \chi z) \mid (p \mid \chi w)\}.
\end{aligned}$$

Put $f(x, y, z, w) . = . (\chi y \mid \psi x) \mid \{(p \mid \chi z) \mid (p \mid \chi w)\}$.

Then $\sim\{(s \mid q) \mid \sim(p \mid s)\} . = : (\exists x, y, x', y') : (z, w, z', w') . f(x, y, z, w) \mid f(x', y', z', w')$,

$(p \mid \sim q) \mid \sim\{(s \mid q) \mid \sim(p \mid s)\} . = : (x, y, x', y') : (\exists b, c, z, w, z', w') .$

$$\{p \mid (\psi b \mid \psi c)\} \mid \{f(x, y, z, w) \mid f(x', y', z', w')\}.$$

Writing $\theta\hat{x}$ for $\sim\chi\hat{x}$, the matrix is equivalent to

$p . \supset . \psi b . \psi c : \supset :. \psi x \supset \theta y . \supset : p . \supset . \theta z . \theta w :. \psi x' \supset \theta y' . \supset : p . \supset . \theta z' . \theta w'$.

This is satisfied by putting $b = x . c = x' . z = w = y . z' = w' = y'$. Hence Prop. The same matrix appears in the next three propositions; only the prefix changes.

$*8{\cdot}351.\ \vdash :. p . \supset . (x) . \psi x : \supset : \{(\exists x) . \chi x\} \mid \{(x) . \psi x\} . \supset . p \mid \{(\exists x) . \chi x\}$

Same matrix as in $*8{\cdot}35$, but prefix $(x, z, w, x', z', w') : (\exists b, c, y, y')$.

Matrix is true if $\theta z . \theta w . \theta z' . \theta w'$.

Assume $\sim\theta z$, and put $y = y' = z . b = x . c = x'$.

We now have $\psi x \supset \theta y . \equiv . \sim \psi x$ and $p . \supset . \theta z . \theta w : \equiv . \sim p$. Hence matrix is equivalent to

$$p . \supset . \psi x . \psi x' : \supset :. \sim \psi x . \supset . \sim p :. \sim \psi x' . \supset : p . \supset . \theta z' . \theta w',$$

which is true. Similarly if $\sim \theta w \vee \sim \theta z' \vee \sim \theta w'$. Hence Prop, by $*8 \cdot 1 \cdot 28$.

$*8 \cdot 352$. $\vdash :. p . \supset . (\exists x) . \psi x : \supset : \{(x) . \chi x\} \mid \{(\exists x) . \psi x\} . \supset . p \mid \{(x) . \chi x\}$

Same matrix, but prefix $(b, c, y, y') : (\exists x, z, w, x', z', w')$.

Satisfied by $x = b . x' = c . z = w = y . z' = w' = y'$. Hence Prop.

$*8 \cdot 353$. $\vdash :. p . \supset . (\exists x) . \psi x : \supset : \{(\exists x) . \chi x\} \mid \{(\exists x) . \psi x\} . \supset . p \mid \{(\exists x) . \chi x\}$

Same matrix, with prefix $(b, c, z, w, z', w') : (\exists x, y, x', y')$.

If ψb is true and θz false, matrix is satisfied by $x = x' = b . y = y' = z$, because these values make $\psi x \supset \theta y$ and $\psi x' \supset \theta y'$ false. Smilarly if ψb is true and θw or $\theta z'$ or $\theta w'$ is false, and if ψc is true and θz, θw, $\theta z'$ or $\theta w'$ is false. It remains to consider $\sim \psi b . \sim \psi c : \vee : \theta z . \theta w . \theta z' . \theta w'$.
The second alternative makes the matrix true, because it gives

$$p . \supset . \theta z . \theta w : p . \supset . \theta z' . \theta w'.$$

The first alternative gives

$$\begin{aligned} &p . \supset . \psi b . \psi c : \supset : \sim p : \\ &\qquad \supset : p . \supset . \theta z . \theta w : p . \supset . \theta z' . \theta w', \end{aligned}$$

so that again the matrix is true. Hence Prop.

This finishes the cases in which one or two of the three constituents of $p \supset q . \supset . s \mid q \supset p \mid s$ remain elementary. It remains to consider the eight cases in which none remains elementary. These all have the same matrix.

$*8 \cdot 36$. $\vdash :. (x) . \phi x . \supset . (x) . \psi x : \supset : \{(x) . \chi x\} \mid \{(x) . \psi x\} . \supset . \{(x) . \phi x\} \mid \{(x) . \chi x\}$

Putting $p . = . (x) . \phi x$, $q . = . (x) . \psi x$, $s . = . (x) . \chi x$, we have

$$\begin{aligned} \sim q . &= . (\exists b, c) . \psi b \mid \psi c, \\ p \mid \sim q . &= : (\exists a) : (b, c) . \phi a \mid (\psi b \mid \psi c), \\ s \mid q . &= . (\exists x, y) . \chi y \mid \psi x, \\ p \mid s . &= . (\exists z, w) . \phi z \mid \chi w, \\ \sim (p \mid s) . &= . (z, w, u, v) . (\phi z \mid \chi w) \mid (\phi u \mid \chi v), \\ (s \mid q) \mid \sim (p \mid s) . &= : (x, y) : (\exists z, w, u, v) . (\chi y \mid \psi x) \mid \{(\phi z \mid \chi w) \mid (\phi u \mid \chi v)\}. \end{aligned}$$

Put $f(x, y, z, w, u, v) . = . (\chi y \mid \psi x) \mid \{(\phi z \mid \chi w) \mid (\phi u \mid \chi v)\}$. Then

$$\begin{aligned} &\sim \{(s \mid q) \mid \sim (p \mid s)\} . = : (\exists x, y, x', y') : (z, w, u, v, z', w', u', v') . \\ &\qquad\qquad f(x, y, z, w, u, v) \mid f(x', y', z', w', u', v'), \\ &(p \mid \sim q) \mid \sim \{(s \mid q) \mid \sim (p \mid s)\} . = : (a, x, y, x', y') : (\exists b, c, z, w, u, v, z', w', u', v') . \\ &\qquad\qquad \{\phi a \mid (\psi b \mid \psi c)\} \mid \{f(x, y, z, w, u, v) \mid f(x', y', z', w', u', v')\}. \end{aligned}$$

Writing $\theta \hat{x}$ for $\sim \chi \hat{x}$, the matrix is equivalent to

$$\begin{aligned} &\phi a . \supset . \psi b . \psi c : \supset :. \psi x \supset \theta y . \supset . \phi z \supset \theta w . \phi u \supset \theta v : \\ &\qquad\qquad \psi x' \supset \theta y' . \supset . \phi z' \supset \theta w' . \phi u' \supset \theta v'. \end{aligned}$$

This is satisfied by $b = x . c = x' . z = u = z' = u' = a . w = v = y . w' = v' = y'$. Hence Prop.

***8·361.** $\vdash :. (x) . \phi x . \supset . (x) . \psi x : \supset : \{(\exists x) . \chi x\} | \{(x) . \psi x\} . \supset . \{(x) . \phi x\} | \{(\exists x) . \chi x\}$

Same matrix, but "all" and "some" are interchanged in arguments to χ, *i.e.* in y, w, v, y', w', v'. The $\exists$-variables are therefore $b, c, y, y', z, z', u, u'$.

If $\sim \phi a$, put $z = u = z' = u' = a$, and matrix is satisfied.

If ϕa is true, matrix is true if $\sim \psi b \vee \sim \psi c$, *i.e.* if $\sim \psi x \vee \sim \psi x'$, since b, c are arbitrary. Assume $\psi x . \psi x'$. Then matrix reduces to

$$\theta y . \supset . \phi z \supset \theta w . \phi u \supset \theta v : \theta y' . \supset . \phi z' \supset \theta w' . \phi u' \supset \theta v'.$$

If $\theta w, \theta v, \theta w', \theta v'$ are all true, this is true.

If $\sim \theta w$, put $y = y' = w$, and matrix is satisfied.

Similarly if $\sim \theta v$, $\sim \theta w'$ or $\sim \theta v'$. Hence Prop.

***8·362.** $\vdash :. (x) . \phi x . \supset . (\exists x) . \psi x : \supset : \{(x) . \chi x\} | \{(\exists x) . \psi x\} . \supset . \{(x) . \phi x\} | \{(x) . \chi x\}$

Matrix as in *8·36. Prefix results from *8·36 by interchanging "all" and "some" among ψ-arguments, *i.e.* b, c, x, x'. Hence Prop results from same substitutions as in *8·36.

***8·363.** $\vdash :. (x) . \phi x . \supset . (\exists x) . \psi x : \supset : \{(\exists x) . \chi x\} | \{(\exists x) . \psi x\} .$
$\supset . \{(x) . \phi x\} | \{(\exists x) . \chi x\}$

Results from interchanging "all" and "some," in *8·361, in the ψ-arguments, viz. b, c, x, x'. The $\exists$-variables are therefore $x, x', y, y', z, z', u, u'$, and the proof proceeds exactly as in *8·361, interchanging x, x' and b, c.

***8·364.** $\vdash :. (\exists x) . \phi x . \supset . (x) . \psi x : \supset : \{(x) . \chi x\} | \{(x) . \psi x\} . \supset . \{(\exists x) . \phi x\} | \{(x) . \chi x\}$

The proposition is what results from *8·36 by interchanging "all" and "some" in the ϕ-arguments, viz. a, z, u, z', u'. Hence the $\exists$-arguments are a, b, c, w, v, w', v'. If θy is true, put $w = v = w' = v' = y$, and the matrix is satisfied. If $\theta y'$ is true, put $w = v = w' = v' = y'$, and the matrix is satisfied. Assume $\sim \theta y . \sim \theta y'$. The matrix is true if $\psi x \supset \theta y$ and $\psi x' \supset \theta y'$ are false, *i.e.*, since $\theta y, \theta y'$ are false, if ψx and $\psi x'$ are true. If ψx is false, put $b = c = x$ and $a = y$; then $\phi a . \supset . \psi b . \psi c$ is false, and the matrix is true. If $\psi x'$ is false, similarly. Hence Prop.

***8·365.** $\vdash :. (\exists x) . \phi x . \supset . (x) . \psi x : \supset : \{(\exists x) . \chi x\} | \{(x) . \psi x\} .$
$\supset . \{(\exists x) . \phi x\} | \{(\exists x) . \chi x\}$

Prop is what results from *8·364 by interchanging "all" and "some" in the χ-arguments, viz. y, w, v, y', w', v'. Hence the $\exists$-arguments are a, b, c, y, y'. Matrix is true if $\theta w . \theta v . \theta w' . \theta v'$. Assume $\sim \theta w$, and put $y = y' = w$. Matrix is true if $\psi x \supset \theta y$ and $\psi x' \supset \theta y'$ are false, *i.e.*, in the present case, if ψx and $\psi x'$ are true. Suppose one of them false, and put $b = x . c = x'$. Then $\psi b . \psi c$ is false. Therefore $\phi a . \supset . \psi b . \psi c$ is false if ϕa is true; therefore the matrix is true if ϕa is true. Therefore if ϕz is true, the matrix is true for $a = z$. Similarly if ϕu, $\phi z'$ or $\phi u'$ is true. But if all are false, matrix is also true. Hence matrix is true when we have $\sim \theta w$ and $\sim \psi x \vee \sim \psi x'$. Similarly for $\sim \theta v$, $\sim \theta w'$ or $\sim \theta v'$ with $\sim \psi x \vee \sim \psi x'$. We saw that matrix can be satisfied

for $\sim\theta w$, $\sim\theta v$, $\sim\theta w'$ or $\sim\theta v'$ with $\psi x \,.\, \psi x'$. Hence it can be satisfied for $\sim\theta w \vee \sim\theta v \vee \sim\theta w' \vee \sim\theta v'$. And we saw that it is true for $\theta w \,.\, \theta v \,.\, \theta w' \,.\, \theta v'$. This completes the cases. Hence Prop.

***8·366.** $\vdash :. (\exists x) \,.\, \phi x \,.\supset.\, (\exists x) \,.\, \psi x : \supset : \{(x) \,.\, \chi x\} \,|\, \{(\exists x) \,.\, \psi x\} \,.$
$\supset . \{(\exists x) \,.\, \phi x\} \,|\, \{(x) \,.\, \chi x\}$

Prop is what results from *8·364 by interchanging "all" and "some" among ψ-arguments, viz. b, c, x, x'. Hence $\exists$-arguments are a, x, x', w, v, w', v'. The proof proceeds as in *8·364, interchanging b, c and x, x'.

***8·367.** $\vdash :. (\exists x) \,.\, \phi x \,.\supset.\, (\exists x) \,.\, \psi x : \supset : \{(\exists x) \,.\, \chi x\} \,|\, \{(\exists x) \,.\, \psi x\} \,.$
$\supset . \{(\exists x) \,.\, \phi x\} \,|\, \{(\exists x) \,.\, \chi x\}$

Prop is what results from *8·365 by interchanging "all" and "some" among ψ-arguments, viz. b, c, x, x'. Hence the $\exists$-arguments are a, x, x', y, y'. The proof proceeds as in *8·365, interchanging b, c and x, x'.

This completes the 26 cases of $p \supset q \,.\supset.\, s|q \supset p|s$. Hence in all the propositions of *1—*5 we can substitute propositions containing one variable. The proofs for propositions containing 2 or 3 or 4 or ... variables are step-by-step the same. Hence the propositions of *1—*5 hold of all first-order propositions.

The extension to second-order propositions, and thence to third-order propositions, and so on, is made by exactly analogous steps. Hence all stroke-functions which can be demonstrated for elementary propositions can be demonstrated for propositions of any order.

It remains to prove $\sim\{(x) \,.\, \phi x\} \,.\equiv.\, (\exists x) \,.\, \sim\phi x$ and similar propositions.

***8·5.** If $F(p, q, r, \ldots)$ is a stroke-function of elementary propositions, and $p, q, r, \ldots$ are replaced by first-order propositions $p_1, q_1, r_1, \ldots$, we shall have

$$p \equiv p_1 . q \equiv q_1 . r \equiv r_1, \ldots \supset : F(p, q, r, \ldots) . \equiv . F(p_1, q_1, r_1, \ldots).$$

This follows from

$$p_1 . = . (x) . \phi x : \supset : p \equiv p_1 . \supset . p_1 | q \equiv p | q . q | p_1 \equiv q | p,$$

$$p_1 . = . (\exists x) . \phi x : \supset : p \equiv p_1 . \supset . p_1 | q \equiv p | q . q | p_1 \equiv q | p,$$

both of which are very easily proved.

APPENDIX B

$*89$. MATHEMATICAL INDUCTION

THE difficulties which arise in connection with mathematical induction when the axiom of reducibility is rejected have been explained in the Introduction to the present edition. Retaining the definition of R_* ($*90{\cdot}01$), we have

$$\vdash :. \, xR_*y \,.\, \equiv : x \in C\text{‘}R : \breve{R}\text{“}\mu \subset \mu \,.\, x \in \mu \,.\, \supset_\mu \,.\, y \in \mu .$$

The "μ" which occurs here as apparent variable must be of some definite order. If κ is a class of classes, and the members of κ are of the order contemplated in the definition of R_*, we cannot infer

$$xR_*y \,.\, \supset : \breve{R}\text{“}p\text{‘}\kappa \subset p\text{‘}\kappa \,.\, x \in p\text{‘}\kappa \,.\, \supset \,.\, y \in p\text{‘}\kappa$$

nor yet $\quad xR_*y \,.\, \supset : \breve{R}\text{“}s\text{‘}\kappa \subset s\text{‘}\kappa \,.\, x \in s\text{‘}\kappa \,.\, \supset \,.\, y \in s\text{‘}\kappa .$

It is necessary, *primâ facie*, to have

$$\alpha \in \kappa \,.\, \supset_\alpha \,.\, \breve{R}\text{“}\alpha \subset \alpha$$

in order to be able to argue from $x \in p\text{‘}\kappa$ to $y \in p\text{‘}\kappa$ or from $x \in s\text{‘}\kappa$ to $y \in s\text{‘}\kappa$. In the following pages, we shall show how to avoid the resulting complications.

Let us denote by "μ_m" a variable class of the mth order, and put

$*89{\cdot}01$. $\quad xR_{*m}y \,.\, = : x \in C\text{‘}R : \breve{R}\text{“}\mu_m \subset \mu_m \,.\, x \in \mu_m \,.\, \supset_{\mu_m} \,.\, y \in \mu_m \quad$ Df

Since every class of a lower order is equal to some class of any given higher order, $R_{*m} \mathrel{\dot\subset} R_{*n}$ if $m > n$. We shall show that

$$m > 5 \,.\, \supset \,.\, R_{*m} = R_{*5} .$$

Hence we take R_{*5} as R_*, and the complications disappear.

In $*90$, substituting R_{*m} for R_* and μ_m for μ and $\phi_m z$ for ϕz, the first proposition involving an invalid induction is $*90{\cdot}17$, where we use the fact that $\overleftarrow{R_*}\text{‘}x$ is hereditary. It is obvious that $\overleftarrow{R_{*m}}\text{‘}x$ is a class of order $m+1$, and therefore, although

$$\breve{R}\text{“}\overleftarrow{R_{*m}}\text{‘}x \subset \overleftarrow{R_{*m}}\text{‘}x ,$$

we cannot infer

$$y \in \overleftarrow{R_{*m}}\text{‘}x \,.\, yR_{*m}z \,.\, \supset \,.\, z \in \overleftarrow{R_{*m}}\text{‘}x .$$

In this case, however, as in many others, there is no difficulty in substituting a valid induction. Put

$$\kappa = \hat{\mu}_m \{ \breve{R}\text{“}\mu_m \subset \mu_m \,.\, x \in \mu_m \} .$$

Then $\overleftarrow{R_{*m}}\text{‘}x = p\text{‘}\kappa$. Now we have not merely $\breve{R}\text{“}p\text{‘}\kappa \subset p\text{‘}\kappa$ but also

$$\mu_m \in \kappa \,.\, \supset \,.\, \breve{R}\text{“}\mu_m \subset \mu_m .$$

Hence the induction is valid.

The proofs of $R_*^2 \subset R_*$ and analogous propositions are easily re-written so as to be valid.

The next difficulty—and this one is more serious—arises in connection with ∗90·31. The present proof uses the fact that

$$x(I \restriction C`R \cup R_* | R) z$$

is a hereditary property of z. But it is a property of a higher order than those by which R_* is defined; *i.e.* if R_* is R_{*m}, then $x(I \restriction C`R \cup R_{*m} | R) z$ is of order $m+1$. Let us prove first

$$R_0 \cup R_* | R \subset R_*,$$

where

∗89·02. $R_0 = I \restriction C`R$ Df

The proof is as follows:

$\supset : xR_*y . yR_*x . \supset . xR_*y . \sim(xR \mid R_*y) .$

[*89·102] $\supset . x = y :. \supset \vdash . \mathrm{Prop}$

***89·114.** $\vdash : R \in \mathrm{Cls} \rightarrow 1 . \breve{R}``\alpha \subset \alpha . x \in \alpha - \breve{R}``\alpha . \supset . \sim(xR \mid R_*x)$ [*89·105]

***89·115.** $\vdash :. R \in \mathrm{Cls} \rightarrow 1 . \breve{R}``\alpha \subset \alpha . x \in \alpha - \breve{R}``\alpha . \supset . R(x \mapsto x) = \iota`x$
[*89·113·114]

We now take as the definition of an inductive class the property proved in $*121 \cdot 24$, *i.e.* we put

$$\text{Cls induct} = \hat{\rho}\{\eta \in \mu \,.\supset_{\eta, y}.\, \eta \cup \iota`y \in \mu : \Lambda \in \mu : \supset_\mu .\, \rho \in \mu\} \quad \text{Df.}$$

That is to say, if $\quad M = \hat{\eta}\hat{\zeta}\{(\exists y) \,.\, \zeta = \eta \cup \iota`y\}$,

we put $\quad \text{Cls induct} = \overleftarrow{M_*}`\Lambda \quad \text{Df.}$

There will be different orders of inductive classes according to the order of μ. μ must be at least of the second order, since $\iota`y$ is of the second order; at least, not much could be proved if we took μ to be of the first order. We put

$$\text{Cls induct}_m = \overleftarrow{M_{*m}}`\Lambda \quad \text{Df.}$$

We have $\quad (\exists \mu_2) \,.\, \Lambda = \mu_2 : (\exists \mu_2) \,.\, \eta = \mu_2 \,.\supset.\, (\exists \mu_2) \,.\, \eta \cup \iota`y = \mu_2$.

Now $(\exists \mu_2) \,.\, \eta = \mu_2$ is a third-order property. Hence

$*89 \cdot 12$. $\vdash : \rho \in \text{Cls induct}_3 \,.\supset.\, (\exists \mu_2) \,.\, \rho = \mu_2$

This proposition is fundamental.

$*89 \cdot 13$. $\vdash :. R \in \text{Cls} \to 1 : \eta \in \mu \,.\supset_{\eta, y}.\, \eta \cup \iota`y \in \mu : \Lambda \in \mu : \sim(xR \mid R_* x) \,.\, xRz : \supset :$
$R(z \mapsto y) \in \mu \,.\supset.\, R(x \mapsto y) \in \mu$

$[*89 \cdot 11 \cdot 111 \cdot 112 \cdot 113]$

Put

$*89 \cdot 131$. $R_m(x \mapsto y) = \overleftarrow{R_{*m}}`x \cap \overrightarrow{R_{*m}}`y \quad$ Df

Then

$$\kappa = \hat{\alpha}_m(\breve{R}``\alpha_m \subset \alpha_m \,.\, x \in \alpha_m) \,.\, \lambda = \hat{\beta}_m(R``\beta_m \subset \beta_m \,.\, y \in \beta_m) \,.\supset.$$
$$R_m(x \mapsto y) = p`\kappa \cap p`\lambda.$$

Thus $R_m(x \mapsto y)$ is a class of order $m+1$. Moreover we have

$*89 \cdot 132$. $\vdash :. R \in \text{Cls} \to 1 \,.\, xRy \,.\supset : \sim(yR \mid R_* y) \,.\supset.\, \sim(xR \mid R_* x)$

Dem.

$\vdash : \sim(yR \mid R_* y) \,.\, xRy \,.\supset.\, (\exists \alpha) \,.\, \breve{R}``\alpha \subset \alpha \,.\, y \in \alpha - \breve{R}``\alpha \,.\, xRy \quad (1)$

$\vdash : \text{Hp} \,.\, \breve{R}``\alpha \subset \alpha \,.\, y \in \alpha - \breve{R}``\alpha \,.\, xRy \,.\, \gamma = \iota`x \cup \iota`y \cup \breve{R}``\alpha \,.$
$\supset.\, \breve{R}``\gamma = \iota`y \cup \overleftarrow{R}`y \cup \breve{R}``\breve{R}``\alpha \,. \quad (2)$
$\supset.\, \breve{R}``\gamma \subset \gamma \quad (3)$

$\vdash :. \sim(yR \mid R_* y) \,.\supset : \sim(yRy) :$
$\supset : xRy \,.\supset.\, x \neq y \quad (4)$

$\vdash : y \in \alpha - \breve{R}``\alpha \,.\, xRy \,.\supset.\, x \sim\in \alpha \quad (5)$

$\vdash .\, (3) \,.\, (7) \,.\supset \vdash : \text{Hp}(2) \,.\supset.\, \sim(xR \mid R_* x) \quad (8)$

$\vdash .\, (1) \,.\, (8) \,.\supset \vdash .\, \text{Prop}$

***89·133.** $\vdash :. R \in \text{Cls} \to 1 : \eta \in \mu \,.\, \supset_{\eta, y} .\, \eta \cup \iota\text{‘}y \in \mu : \Lambda \in \mu : xRz : \supset :$
$$\sim(zR \,|\, R_{*}z) \,.\, R\,(z \mapsto y) \in \mu \,.\, \supset .\, \sim(xR \,|\, R_{*}x) \,.\, R\,(x \mapsto y) \in \mu$$
[*89·13·132]

***89·14.** $\vdash :. R \in \text{Cls} \to 1 \,.\, \sim(yR \,|\, R_{*m}y) \,.\, \supset : xR_{*(m+1)}\,y \,.\, \supset .$
$$R_m\,(x \mapsto y) \in \text{Cls induct}_{m+1}$$

Dem.

By *89·133, $\sim(zR \,|\, R_{*m}z) \,.\, R_m\,(z \mapsto y) \in \mu_{m+1}$ is a hereditary property of z if
$$\eta \in \mu_{m+1} \,.\, \supset_{\eta, y} .\, \eta \cup \iota\text{‘}y \in \mu_{m+1} : \Lambda \in \mu_{m+1}.$$
Moreover this property is of order $m+1$. And by *89·113, y has this property if $\sim(yR \,|\, R_{*m}y)$. Hence x has this property if $xR_{*(m+1)}\,y$. Hence with this hypothesis we have
$$\eta \in \mu_{m+1} \,.\, \supset_{\eta, y} .\, \eta \cup \iota\text{‘}y \in \mu_{m+1} : \Lambda \in \mu_{m+1} : \supset_{\mu_{m+1}} .\, R_m\,(x \mapsto y) \in \mu_{m+1},$$
i.e. $$R_m\,(x \mapsto y) \in \text{Cls induct}_{m+1},$$
which was to be proved.

***89·15.** $\vdash : R \in \text{Cls} \to 1 \,.\, \breve{R}\text{‘‘}\alpha_m \subset \alpha_m \,.\, y \in \alpha_m - \breve{R}\text{‘‘}\alpha_m \,.\, \supset :$
$$xR_{*(m+1)}\,y \,.\, \supset .\, R_m\,(x \mapsto y) \in \text{Cls induct}_{m+1} \qquad [*89·114·14]$$

We have $$R_{m+1}\,(x \mapsto y) \subset R_m\,(x \mapsto y),$$
$$\text{Cls induct}_{m+1} \subset \text{Cls induct}_m.$$
The next point is to prove
$$\rho \in \text{Cls induct}_m \,.\, \gamma \subset \rho \,.\, \supset .\, \gamma \in \text{Cls induct}_m.$$
This can be proved for Cls induct_3, and extended to any other order of inductive classes. The proof is as follows.

***89·16.** $\vdash : \alpha \sim\in \text{Cls induct}_3 \,.\, \gamma \in \text{Cls induct}_3 \,.\, \supset .\, \exists !\, \alpha - \gamma$

Dem.

$\text{Hp} \,.\, \supset : (\exists \mu_3) : \Lambda \in \mu_3 : \beta \in \mu_3 \,.\, \supset_{\beta, y} .\, \beta \cup \iota\text{‘}y \in \mu_3 : \gamma \in \mu_3 \,.\, \alpha \sim\in \mu_3$ (1)

$(1) \,.\, (6) \,.\, \supset \vdash .$ Prop

***89·17.** $\vdash : \gamma \in \text{Cls induct}_3 \,.\, \alpha \subset \gamma \,.\, \supset .\, \alpha \in \text{Cls induct}_3$ [*89·16 . Transp]

It follows that, with the hypothesis of *89·15, $R_m\,(x \mapsto y)$, $R_{m+1}\,(x \mapsto y)$, etc. are all of them inductive classes of the $(m+1)$th or any lower order.

$*89{\cdot}18.\quad \vdash :. R \in \mathrm{Cls} \to 1 \,.\, y, z \in \overleftarrow{R_{*3}}\text{‘}x \,.\, \sim(yR \,|\, R_{*2}y) \,.\, \supset : yR_{*3}z \,.\, \vee \,.\, zR_{*3}y$

Dem.

Put $\xi = R_3(x \mapsto y) \cap R_3(x \mapsto z)$.

$\vdash . *89{\cdot}12{\cdot}14{\cdot}17 \,.\, \supset \vdash : \mathrm{Hp} \,.\, \supset . \, \xi \in \mathrm{Cls}_2$, *i.e.* ξ is a class of the second order (1)

$\vdash :. \mathrm{Hp} \,.\, \sim(yR_{*3}z) \,.\, \sim(zR_{*3}y) \,.\, \supset : u \in \xi \,.\, \supset . \, uR_{*3}y \,.\, uR_{*3}z \,.\, u \neq y \,.\, u \neq z \,.$

$[*89{\cdot}102] \qquad \supset . \, \breve{R}\text{‘}uR_{*3}y \,.\, \breve{R}\text{‘}uR_{*3}z \,.$

$[\mathrm{Hp}] \qquad \supset . \, \breve{R}\text{‘}u \in \xi$ (2)

$\vdash . (1) . (2) . \supset \vdash : \mathrm{Hp}(2) \,.\, \supset . \, y \in \xi$ (3)

$\vdash : \mathrm{Hp}(2) \,.\, \supset . \, y \sim\in \xi$ (4)

$\vdash . (3) . (4) . \supset \vdash :. \mathrm{Hp} \,.\, \supset : yR_{*3}z \,.\, \vee \,.\, zR_{*3}y :. \supset \vdash . \mathrm{Prop}$

$*89{\cdot}19.\quad \vdash : R \in \mathrm{Cls} \to 1 \,.\, \breve{R}\text{‘‘}\mu_2 \subset \mu_2 \,.\, \lambda = \overleftarrow{R_{*3}}\text{‘}x \cap \mu_2 - \breve{R}\text{‘‘}\mu_2 \,.\, \supset . \, \lambda \in 0 \cup 1$

Dem.

$\vdash : \mathrm{Hp} \,.\, y, z \in \lambda \,.\, y \neq z \,.\, \xi = R_2(x \mapsto y) \cap R_2(x \mapsto z) \,.\, \supset . \, \breve{R}\text{‘‘}\xi \subset \xi \,.\, x \in \xi$ [as above]

$[*89{\cdot}12{\cdot}15{\cdot}17] \qquad \supset . \, y, z \in \xi$ (1)

$\vdash : \mathrm{Hp}(1) \,.\, \supset . \, y, z \sim\in \xi$ (2)

$\vdash . (1) . (2) . \supset \vdash . \mathrm{Prop}$

$*89{\cdot}2.\quad \vdash : R \in \mathrm{Cls} \to 1 \,.\, xR_{*3}y \,.\, R_2(y \mapsto y) \in \mathrm{Cls\ induct}_3 \,.\, \supset . \, R_2(x \mapsto y) \in \mathrm{Cls\ induct}_3$

Dem.

As in $*89{\cdot}11{\cdot}111{\cdot}112$,

$\vdash :. R \in \mathrm{Cls} \to 1 \,.\, xRz \,.\, \supset :$

$R(x \mapsto y) = \iota\text{‘}x \cup R(z \mapsto y) \,.\, \vee \,.\, R(x \mapsto y) = \iota\text{‘}x \,.\, \vee \,.\, R(x \mapsto y) = \Lambda$ (1)

$\vdash . (1) . \supset \vdash :. \mathrm{Hp}(1) : \Lambda \in \mu : \alpha \in \mu \,.\, \supset_{\alpha, u} . \, \alpha \cup \iota\text{‘}u \in \mu : \supset :$

$R(z \mapsto y) \in \mu \,.\, \supset . \, R(x \mapsto y) \in \mu$ (2)

$\vdash . (2) . \supset \vdash : R \in \mathrm{Cls} \to 1 \,.\, xR_{*3}y \,.\, R_2(y \mapsto y) \in \mathrm{Cls\ induct}_3 \,.\, \supset .$

$R_2(x \mapsto y) \in \mathrm{Cls\ induct}_3 : \supset \vdash . \mathrm{Prop}$

To deal further with the case in which $y(R \,|\, R_{*2})y$, proceed as follows: Having proved

$R \in \mathrm{Cls} \to 1 \,.\, xR_{*3}y \,.\, R_2(y \mapsto y) \in \mathrm{Cls\ induct}_3 \,.\, \supset . \, R_2(x \mapsto y) \in \mathrm{Cls\ induct}_3$,

we have to prove $R_2(y \mapsto y) \in \mathrm{Cls\ induct}_3$; for this purpose, put

$$S = (-\iota\text{‘}y) \upharpoonleft R.$$

Then $\qquad S \in \mathrm{Cls} \to 1 \,.\, S \mathrel{\subseteq} R.$

Observe that $\qquad yRy \,.\, \supset . \, R(y \mapsto y) = \iota\text{‘}y,$

$\qquad yR^2y \,.\, \supset . \, R(y \mapsto y) = \iota\text{‘}y \cup \iota\text{‘}\breve{R}\text{‘}y.$

Assume, therefore, $\qquad \sim(yRy) \,.\, \sim(yR^2y).$

We have $\breve{S}\text{‘‘}\mu = \breve{R}\text{‘‘}(\mu - \iota\text{‘}y) \,.\, S\text{‘‘}\mu = R\text{‘‘}\mu - \iota\text{‘}y$. Hence

$$\breve{S}\text{‘‘}\mu \subset \mu \,.\, \breve{R}\text{‘}y \in \mu \,.\, \equiv . \, \breve{R}\text{‘‘}\mu \subset \mu \,.\, \breve{R}\text{‘}y \in \mu,$$

$$S\text{‘‘}\mu \subset \mu \,.\, y \in \mu \,.\, \equiv . \, R\text{‘‘}\mu \subset \mu \,.\, y \in \mu.$$

Hence $\qquad \overleftarrow{S_*}\text{‘}\breve{R}\text{‘}y = \overleftarrow{R_*}\text{‘}\breve{R}\text{‘}y \,.\, \overrightarrow{S_*}\text{‘}y = \overrightarrow{R_*}\text{‘}y.$

Hence $\qquad S_2(\breve{R}\text{‘}y \mapsto y) = R_2(\breve{R}\text{‘}y \mapsto y) = R_2(y \mapsto y)$

because $y\,(R \,|\, R_{*2})\,y$.

Moreover we have $\sim(yS \,|\, S_* y)$ because $y \sim\in \mathrm{D}\text{‘}S$.

Hence by $*89{\cdot}14$, $R_2(y \mapsto y) \in \mathrm{Cls\ induct}_3$. Hence generally:

$*89{\cdot}201.\ \vdash : R \in \mathrm{Cls} \to 1 \,.\, xR_{*3}y \,.\, \supset \,.\, R_2(x \mapsto y) \in \mathrm{Cls\ induct}_3$

We have $\qquad R_3(x \mapsto y) \subset R_2(x \mapsto y).$

Hence by $*89{\cdot}17$, $R_2(x \mapsto y) \in \mathrm{Cls\ induct}_3 \,.\, \supset \,.\, R_3(x \mapsto y) \in \mathrm{Cls\ induct}_3$. Hence

$*89{\cdot}21.\ \vdash : R \in \mathrm{Cls} \to 1 \,.\, \supset \,.\, R_3(x \mapsto y) \in \mathrm{Cls\ induct}_3$

because $\qquad \sim(xR_{*3}y) \,.\, \supset \,.\, R_3(x \mapsto y) = \Lambda.$

$*89{\cdot}22.\ \vdash :. R \in \mathrm{Cls} \to 1 \,.\, y, z \in \overleftarrow{R_{*3}}\text{‘}x \,.\, \supset : yR_{*3}z \,.\, \vee \,.\, zR_{*3}y$

[Proof as in $*89{\cdot}18$, using $*89{\cdot}21$ instead of $*89{\cdot}14$]

$*89{\cdot}221.\ \mathrm{Potid}_m\text{‘}R = \overrightarrow{(R_{\mathrm{ts}})_m}\text{‘}R_0 \quad \mathrm{Df}$

$*89{\cdot}23.\ \vdash :. S, T \in \mathrm{Potid}_3\text{‘}R \,.\, \supset : SR_{\mathrm{ts}3}T \,.\, \vee \,.\, TR_{\mathrm{ts}3}S \qquad \left[*89{\cdot}22 \dfrac{\mathrm{Cnv}\text{‘}|\,R}{R}\right]$

$*89{\cdot}24.\ \vdash : R \in \mathrm{Cls} \to 1 \,.\, \breve{R}\text{“}\lambda \subset \lambda \,.\, x \in \lambda \,.\, \supset \,.\, \overleftarrow{R_{*3}}\text{‘}x \subset \lambda$

Here λ is assumed to be of more than the third order.

Dem.

$\vdash :. \mathrm{Hp} \,.\, y \in \overleftarrow{R_{*3}}\text{‘}x - \lambda \,.\, \supset : z \in \lambda \cap R_3(x \mapsto y) \,.\, \supset \,.\, z \neq y \,.$

$\supset \,.\, \breve{R}\text{‘}z \in \lambda \cap R_3(x \mapsto y) \qquad (1)$

$\vdash \,.\, *89{\cdot}21{\cdot}17{\cdot}12 \,.\, \supset \vdash : \mathrm{Hp} \,.\, \supset \,.\, (\exists \mu_2) \,.\, \lambda \cap R_3(x \mapsto y) = \mu_2 \qquad (2)$

$\vdash \,.\, (1) \,.\, (2) \,.\, \supset \vdash : \mathrm{Hp}(1) \,.\, \supset \,.\, (\exists \mu_2) \,.\, \lambda \cap R_3(x \mapsto y) = \mu_2 \,.\, \breve{R}\text{“}\mu_2 \subset \mu_2 \,.\, x \in \mu_2 \,.$

$\supset \,.\, \overleftarrow{R_{*3}}\text{‘}x \subset \lambda \cap R_3(x \mapsto y) \qquad (3)$

$\vdash \,.\, (3) \,.\, \supset \vdash :. \mathrm{Hp} \,.\, \supset : y \in \overleftarrow{R_{*3}}\text{‘}x - \lambda \,.\, \supset \,.\, y \in \lambda :$

$\supset : \overleftarrow{R_{*3}}\text{‘}x \subset \lambda :. \supset \vdash \,.\, \mathrm{Prop}$

Hence if λ is an inductive class, it can be used in an induction no matter what its order may be, if $R \in \mathrm{Cls} \to 1$.

$*89{\cdot}25.\ \vdash : R \in 1 \to \mathrm{Cls} \,.\, \supset \,.\, R_3(x \mapsto y) \in \mathrm{Cls\ induct}_3 \qquad \left[*89{\cdot}21 \dfrac{\breve{R}}{R}\right]$

$*89{\cdot}26.\ \vdash :. R \in 1 \to \mathrm{Cls} \,.\, y, z \in \overrightarrow{R_{*3}}\text{‘}x \,.\, \supset : yR_{*3}z \,.\, \vee \,.\, zR_{*3}y \qquad \left[*89{\cdot}22 \dfrac{\breve{R}}{R}\right]$

$*89{\cdot}27.\ \vdash : R \in 1 \to \mathrm{Cls} \,.\, R\text{“}\lambda \subset \lambda \,.\, x \in \lambda \,.\, \supset \,.\, \overrightarrow{R_{*3}}\text{‘}x \subset \lambda \qquad \left[*89{\cdot}24 \dfrac{\breve{R}}{R}\right]$

***89·28.** $\vdash : R \epsilon (1 \to \mathrm{Cls}) \cup (\mathrm{Cls} \to 1) . \supset . R_{*3} = \dot{s}`\mathrm{Potid}_3`R$

$*89{\cdot}33$. $\vdash . R_{*(5+m)} = R_{*5}$

Dem.

As in $*89{\cdot}32$, $\vdash . \overrightarrow{R_{*(5+m)}}`x = s`\overrightarrow{(R_\epsilon)_{*(3+m)}}`x$

$[*89{\cdot}29]$ $= s`\overrightarrow{(R_\epsilon)_{*3}}`x$

$[*89{\cdot}32]$ $= \overrightarrow{R_{*5}}`x . \supset \vdash .$ Prop

$*89{\cdot}34$. $\vdash : y R_{*5} x . x \epsilon \lambda . R``\lambda \subset \lambda . \supset . y \epsilon \lambda$ $[*89{\cdot}33]$

Here λ is supposed to be of any order, however high. Hence, so far as mathematical induction is concerned, all proofs remain valid without the axiom of reducibility provided "R_*" is understood to mean "R_{*5}."

APPENDIX C

TRUTH-FUNCTIONS AND OTHERS

IN the Introduction to the present edition we have assumed that a function can only enter into a proposition through its values. We have in fact assumed that a matrix $f ! (\phi ! \hat{z})$ always arises through some stroke-function

$$F(p, q, r, \ldots)$$

by substituting $\phi ! a$, $\phi ! b$, $\phi ! c$, ... for some or all of p, q, r, ..., and that all other functions of functions are derivable from such matrices by generalization —*i.e.* by replacing some or all of a, b, c, ... by variables, and taking "all values" or "some value."

The uses which we have made of this assumption can be validated by definition, even if the assumption is not universally true. That is to say, we can decide that mathematics is to confine itself to functions of functions which obey the above assumption. This amounts to saying that mathematics is essentially extensional rather than intensional. We might, on this ground, abstain from the inquiry whether our assumption is universally true or not. The inquiry, however, is important on its own account, and we shall, in what follows, suggest certain considerations without arriving at a dogmatic conclusion.

There is a prior question, which is simpler, and that is the question whether all functions of propositions are truth-functions. Or, more precisely, can all propositions which do not contain apparent variables be built up from atomic propositions by means of the stroke? If this were the case, we should have, if $f\hat{p}$ is any function of propositions,

$$p \equiv q \,.\supset.\, fp \equiv fq.$$

Consequently, according to the definition $*13{\cdot}01$,

$$p \equiv q \,.\supset.\, p = q.$$

There will thus be only two propositions, one true and one false. This was Frege's point of view, but it is one which cannot easily be accepted. Frege maintained that every proposition is a proper name, either for the true or for the false. On grounds not connected with our present question, we cannot regard propositions as names; but that does not decide the question whether equivalent propositions are identical. It is this latter question that concerns us. That is to say, we have to consider whether, or in what sense, there are functions fp which are true for some true values of p and false for other true values of p.

Two obvious *primâ facie* instances are "A believes p" and "p is about A." We may take these instances as crucial. If A believes p and p is true, it does

not follow that A believes every other true proposition q; nor, if A believes p, and p is false, does it follow that A believes every other false proposition q. Again, the proposition "A is mortal" is about A; but the proposition "B is mortal," which is equally true, is not about A. Thus the function "p is about A" is not a truth-function of p. This instance is important, because the notation "ϕx" is used to denote a proposition about x, and thus the conception involved *seems* to be presupposed in the whole procedure of propositional functions.

We must, to begin with, distinguish between a proposition as a fact and a proposition as a vehicle of truth or falsehood. The following series of black marks: "Socrates is mortal," is a fact of geography. The noise which I should make if I were to say "Socrates is mortal" would be a fact of acoustics. The mental occurrence when I entertain the belief "Socrates is mortal" is a fact of psychology. None of these introduces the notion of truth or falsehood, which is, for logic, the essential characteristic of propositions. We shall return in a moment to the consideration of propositions as facts.

When we say that truth or falsehood is, for logic, the essential characteristic of propositions, we must not be misunderstood. It does not matter, for mathematical logic, what constitutes truth or falsehood; all that matters is that they divide propositions into two classes according to certain rules. Let us take a set of marks

$$x_1, x_2, \ldots x_{2n-1}, x_{2n}.$$

Let us put, as unexplained assertions,

$$T(x_{2m+1}) \quad (m < n),$$
$$F(x_{2m}) \quad (m \leqslant n).$$

Let us further introduce the symbol $x_r \mid x_s$, and assume

$$T(x_r \mid x_s) \text{ if } F(x_r) \text{ or } F(x_s);$$
$$F(x_r \mid x_s) \text{ if } T(x_r) \text{ and } T(x_s).$$

Assume further that, if p, q, s are any one of the x's or any combination of them by means of the stroke, the above rules are to apply to $p \mid q$, etc., and further we are to have:

$$T\{p \mid (p \mid p)\},$$
$$T\{p \supset q \,.\supset.\, s \mid q \supset p \mid s\},$$

where "$p \supset q$" means "$p \mid (q \mid q)$." Further: given $T\{p \mid (q \mid r)\}$ and $T(p)$, we are to have $T(r)$.

Taking the above as mere conventional rules, all the logic of molecular propositions follows, replacing "$\vdash . p$" by "$T(p)$."

Thus from the formal point of view it is irrelevant what constitutes truth or falsehood: all that matters is that propositions are divided into two classes according to certain rules. It does not matter what propositions are, so long as we are content to regard our primitive propositions as defining hypotheses,

not as truths. (From a philosophical point of view, this formal procedure may be shown to presuppose the non-formal interpretation of our primitive propositions; but that does not matter for our present purpose.)

Throughout the logic of molecular propositions, we do not want to know anything about propositions except whether they are true or false. Further, we are concerned only with those combinations of propositions which are true in virtue of the rules, whether their constituent propositions are true or false. That is—to take the simplest illustration—we assert $p \mid (p \mid p)$, but we never assert any proposition p that has not some suitable molecular structure, although we believe that half of such propositions are true. Our assertions depend always upon structure, never upon the mere fact that some proposition is true.

A new situation arises, however, when we replace p by $\phi ! x$. For example,

we have $\quad \vdash . p \mid (p \mid p)$

and we infer $\quad \vdash . \phi ! x \mid (\phi ! x \mid \phi ! x)$.

We cannot *explain* the notation $\phi ! x$ without introducing characteristics of propositions other than their truth or falsehood. Take for example the primitive proposition (∗8·11)

$$\vdash . (\exists x) . \phi ! x \mid (\phi ! a \mid \phi ! b).$$

The truth of this proposition depends upon the *form* of the constituent propositions $\phi ! x$, $\phi ! a$, $\phi ! b$, not simply upon their truth or falsehood. It cannot be replaced by

$$\text{“} \vdash . (\exists p) . p \mid (q \mid r) \text{,”}$$

which is true but does not have the desired consequences. We are therefore compelled to consider what is meant by saying that a proposition is of the form $\phi ! a$ (where a is some constant). This brings us back to "A occurs in p," which we gave above as an example of a function which is not a truth-function. And this, we shall find, brings us back to the proposition as fact, in opposition to the proposition as true or false.

Let us revert to our two instances: "A believes p" and "p is about A." We shall avoid certain psychological difficulties if we take, to begin with, "A asserts p" instead of "A believes p." Suppose "p" is "Socrates is Greek." A word is a class of similar noises. Thus a person who asserts "Socrates is Greek" is a person who makes, in rapid succession, three noises, of which the first is a member of the class "Socrates," the second a member of the class "is," and the third a member of the class "Greek." This series of events is part of the series of events which constitutes the person. If A is the series of events constituting the person, α is the class of noises "Socrates," β the class "is," and γ the class "Greek," then "A asserts that Socrates is Greek" is (omitting the rapidity of the succession)

$$(\exists x, y, z) . x \epsilon \alpha . y \epsilon \beta . z \epsilon \gamma . x \downarrow y \cup x \downarrow z \cup y \downarrow z \subset A.$$

It is obvious that this is not a function of p as p occurs in a truth-function.

If we now take up "A believes p," we find the matter rather more complicated, owing to doubt as to what constitutes belief. Some people maintain that a proposition must be expressed in words before we can believe it; if that were so, there would not, from our point of view, be any vital difference between believing and asserting. But if we adopt a less unorthodox standpoint, we shall say that when a man believes "Socrates is Greek" he has simultaneously two thoughts, one of which "means" Socrates while the other "means" Greek, and these two thoughts are related in the way we call "predication." It is not necessary for our purposes to define "meaning," beyond noticing that two different thoughts may "have the same meaning." The relation "having the same meaning" is symmetrical and transitive; moreover, if two thoughts "have the same meaning," either can replace the other in any belief without altering its truth-value. Thus we have one class of thoughts, called "Socrates," which all "have the same meaning"; call this class α. We have another class of thoughts, called "Greek," which all "have the same meaning"; call this class β. Call the relation of predication between two thoughts P. (This is the relation which holds between our thought of the subject and our thought of the predicate when we believe that the subject has the predicate. It is wholly different from the relation which holds between the subject and the predicate when our belief is true.) Then "A believes that Socrates is Greek" is

$$(\exists x, y) . x \epsilon \alpha . y \epsilon \beta . xPy . x, y \epsilon C^{\prime}A.$$

Here, again, the proposition as it occurs in truth-functions has disappeared.

It is not necessary to lay any stress upon the above analysis of belief, which may be completely mistaken. All that is intended is to show that "A believes p" may very well not be a function of p, in the sense in which p occurs in truth-functions.

We have now to consider "p is about A," *e.g.* "'Socrates is Greek' is about Socrates." Here we have to distinguish (1) the fact, (2) the belief, (3) the verbal proposition. The fact and the belief, however, do not raise separate problems, since it is fairly clear that Socrates is a constituent of the fact in the same sense in which the thought of Socrates is a constituent of the belief. And the verbal proposition raises no difficulty, since each instance of the verbal proposition is a series containing a part which is an instance of "Socrates." That is to say, "Socrates" (the word) is a class of series of noises, say λ; and "Socrates is Greek" is another class of series, say μ; and the fact that "Socrates" occurs in "Socrates is Greek" is

$$P \epsilon \mu . \supset . (\exists Q) . Q \epsilon \lambda . Q \subset P.$$

Thus we are left with the question: What do we mean by saying that Socrates is a constituent of the fact that Socrates is Greek? This raises the whole problem of analysis. But we do not need an ultimate answer; we only need

an answer sufficient to throw light on the question whether there are functions of propositions which are not truth-functions.

There are those who deny the legitimacy of analysis. Without admitting that they are in the right, we can frame a theory which they need not reject. Let us assume that facts are capable of various kinds of resemblances and differences. Two facts may have particular-resemblance; then we shall say that they are about the same particular. Again they may have predicate-resemblance, or dyadic-relation-resemblance, or etc. We shall say that a fact is about only one particular if any two facts which have particular-resemblance to the given fact have particular-resemblance to each other. Given such a fact, we may define its one particular as the class of all facts having particular-resemblance to the given fact. In that case, to say that Socrates is a constituent of the fact that Socrates is Greek (assuming conventionally that Socrates is a particular) is to say that the fact is a member of the class of facts which is Socrates. In the case of a belief about Socrates, which is itself a fact composed of thoughts, we shall say that a belief is about Socrates if it is one of the class of facts constituting a certain idea which "means" Socrates in whatever sense we may give to "meaning." Here an "idea" is taken to be a class of psychical facts, say all the beliefs which "refer to" Socrates.

We can define predicates by a similar procedure. Take a fact which is only capable of two kinds of resemblance such as we are considering, namely particular-resemblance and predicate-resemblance; such a fact will be a subject-predicate fact. The predicate involved in it is the class of facts to which it has predicate-resemblance.

We shall assume also various kinds of difference: particular-difference, predicate-difference, etc. These are not necessarily incompatible with the corresponding kind of resemblance; *e.g.* $R(x, x)$ and $R(x, y)$ have both particular-resemblance in respect of x and particular-difference in respect of y. This enables us to define what is meant by saying that a particular occurs twice in a fact, as x occurs twice in $R(x, x)$. First: $R(x, x)$ is a dyadic-relation-fact because it is capable of dyadic-relation-resemblance to other facts; second: any two facts having particular-resemblance to $R(x, x)$ have particular-resemblance to each other. This is what we mean by saying that $R(x, x)$ is a dyadic-relation-fact in which x occurs twice, not a subject-predicate fact. Take next a triadic-relation-fact $R(x, x, z)$. This is, by definition, a triadic-relation-fact because it is capable of triadic-relation-resemblance. The facts having particular-resemblance to $R(x, x, z)$ can be divided into two groups (not three) such that any two members of one group have particular-resemblance to each other. This shows that there is repetition, but not whether it is x or z that is repeated. The facts of the one group are $R(x, x, c)$ for varying c; the facts of the other are $R(a, b, z)$ for varying a and b. Each fact of the group $R(x, x, c)$ belongs to only two groups constituted by particular-resemblance, whereas

the facts of the group $R(a, b, z)$, except when it happens that $a = b$, belong to three groups constituted by particular-resemblance. This defines what is meant by saying that x occurs twice and z once in the fact $R(x, x, z)$. It is obvious that we can deal with tetradic etc. relations in the same way.

According to the above, when we say that Socrates is a constituent of the fact that Socrates is Greek, we mean that this fact is a member of the class of facts which is Socrates.

When we use the notation "$\phi ! x$" to denote a proposition in which "x" occurs, it is a fact that "x" occurs in "$\phi ! x$," but we do not need to assert the fact; the fact does its work without having to be asserted. It is also a fact that, if "x" occurs in a proposition p, and p asserts a fact, then x is a constituent of that fact. This is not a law of logic, but a law of language. It might be false in some languages. For instance, in former days, when a crime was committed in India, the indictment stated that it was committed "in the manor of East Greenwich." These words did not denote any constituents of the fact. But a logical language avoids fictions of this kind.

The notation for functions is an illustration of Wittgenstein's principle, that a logical symbol must, in certain formal respects, resemble what it symbolizes. All the facts of which x is a constituent, according to the above, constitute a certain class defined by particular-resemblance. The various symbols $\phi x, \psi x, \chi x, \ldots$ also all resemble each other in a certain respect, namely that their right-hand halves are very similar (not *exactly* similar, because no two x's are exactly alike). The symbols $R(x, x)$, $R(x, x, z)$, etc. are appropriate to their meanings for similar reasons. The symbols are *used* before their suitability can be explained. To explain *why* "ϕx" is a suitable symbol for a proposition about x is, as we have seen, a complicated matter. But to use the symbol is not a complicated matter. Our symbolism, as a set of facts, resembles, in certain logical respects, the facts which it is to symbolize. This makes it a good symbolism. But in using it we do not presuppose the explanation of why it is good, which belongs to a later stage. And so the notation "ϕx" can be used without first explaining what we mean by "a proposition about x."

We are now in a position to deal with the difference between propositions considered factually and propositions as vehicles of truth and falsehood. When we say "'Socrates' occurs in the proposition 'Socrates is Greek,'" we are taking the proposition factually. Taken in this way, it is a class of series, and 'Socrates' is another class of series. Our statement is only true when we take the proposition and the name as classes. The particular 'Socrates' that occurs at the beginning of our sentence does not occur in the proposition 'Socrates is Greek'; what is true is that another particular closely resembling it occurs in the proposition. It is therefore absolutely essential to all such statements to take words and propositions as classes of similar occurrences, not as single occurrences. But when we assert a proposition, the single occurrence is all

that is relevant. When I assert "Socrates is Greek," the particular occurrences of the words have meaning, and the assertion is made by the particular occurrence of that sentence. And to say of that sentence "'Socrates' occurs in it" is simply false, if I mean the 'Socrates' that I have just written down, since it was a different 'Socrates' that occurred in it. Thus we conclude:

A proposition as the vehicle of truth or falsehood is a particular occurrence, while a proposition considered factually is a class of similar occurrences. It is the proposition considered factually that occurs in such statements as "A believes p" and "p is about A."

Of course it is possible to make statements about the particular fact "Socrates is Greek." We may say how many centimetres long it is; we may say it is black; and so on. But these are not the statements that a philosopher or logician is tempted to make.

When an assertion occurs, it is made by means of a particular fact, which is an instance of the proposition asserted. But this particular fact is, so to speak, "transparent"; nothing is said about it, but by means of it something is said about something else. It is this "transparent" quality which belongs to propositions as they occur in truth-functions. This belongs to p when p is asserted, but not when we say "p is true." Thus suppose we say: "All that Xenophon said about Socrates is true." Put

$$X(p) \,.\!=.\, \text{Xenophon asserted } p,$$
$$S(p) \,.\!=.\, p \text{ is about Socrates.}$$

Then our statement is

$$X(p) \,.\, S(p) \,.\supset_p .\, p \text{ is true.}$$

Here the occurrence of p is not "transparent." But if we say

$$x \in \alpha \,.\supset_x .\, \phi\,!\,x$$

we are asserting $\phi\,!\,x$ for a whole class of values of x, and yet "$\phi\,!\,x$" still has a "transparent" occurrence. The essential difference is that in the former case we speak *about* the symbol or belief, whereas in the latter we merely use it to speak about something else. This is the point which distinguishes the occurrences of propositions in mathematical logic from their occurrences in non-truth-functions.

Let us endeavour to give greater definiteness to this point. Take the statement "Socrates had all the predicates that Xenophon said he had." Let the series of events which was Xenophon be called X. Then if Xenophon attributed the predicate α to Socrates, we might appear to have (writing $x \downarrow y \downarrow z \downarrow w$ for the series x, y, z, w)

$$\text{Socrates} \downarrow \text{had} \downarrow \text{predicate} \downarrow \alpha \Subset X.$$

Thus our assertion would be

$$\text{Socrates} \downarrow \text{had} \downarrow \text{predicate} \downarrow \alpha \Subset X \,.\supset_\alpha .\, \text{Socrates had predicate } \alpha.$$

Here, however, there is an ambiguity. On the left, "Socrates," "had," "predicate," and "α" occur as noises; on the right they occur as symbols. This

ambiguity amounts to a fallacy. For, in fact, what I write on paper is not the noise that Xenophon made, but a symbol for that noise. Thus I am using one symbol "Socrates" in two senses: (a) to mean the noise that Xenophon made on a certain occasion, (b) to mean a certain man. We must say:

If Xenophon made a series of noises which mean what is meant by "Socrates had the predicate α," then what this means is true.

For example: If Xenophon said "Socrates was wise," then what is meant by "Socrates was wise" is true.

But this does not assert that Socrates was wise. When I actually assert that Socrates was wise, I say something which cannot be said by talking about the words I use in saying it; and when I assert that Socrates was wise, although an instance of the proposition occurs, yet I do not say anything whatever about the proposition—in particular I do not say that it is true. This is an inference, not logical, but linguistic.

If the above considerations in any way approximate to the truth, we see that there is an absolute gulf between the assertion of a proposition and an assertion about the proposition. The p that occurs when we assert p and the p that occurs in "A asserts p" are by no means identical. The occurrence of propositions as asserted is simpler than their occurrence as something spoken about. In the assertion of a proposition, and in the assertion of any molecular function of a proposition, the proposition does not occur, if we mean by the proposition the p that occurs in such propositions as "A asserts p" or "p is about A." When these latter are analysed, they are found not to conflict with the view that propositions, in the sense in which they occur when they are asserted, only occur in truth-functions.

When p is asserted, p does not really occur, but the constituents of p occur, or an instance of p occurs. The same is true when a molecular proposition containing p is asserted. Thus we cannot infer $p = q$, because here p and q occur in a sense in which they do not occur when molecular propositions containing them are asserted.

Similar considerations apply to propositional functions. Suppose there are two predicates α and β which are always found together; we may still say that they are two, on the ground that $\alpha(x)$ and $\beta(x)$ are facts which do not have predicate-resemblance. But the propositional function $\alpha(\hat{x})$ is solely to be used in building up matrices by means of the stroke. The predicate α is a class of facts, whereas the propositional function $\alpha(\hat{x})$ is merely a symbolic convenience in speaking about certain propositions. Thus we may have $\alpha(\hat{x}) = \beta(\hat{x})$ without having $\alpha = \beta$. In this way we escape the *primâ facie* paradoxes of the theory that propositions only occur in truth-functions and propositional functions only occur through their values. The paradoxes rest on the confusion between factual and assertive propositions.

LIST OF DEFINITIONS

CONTENTS OF VOLUME II

PREFATORY STATEMENT OF SYMBOLIC CONVENTIONS

THE purpose of the following observations is to bring together in one discussion various explanations which are required in applying the theory of types to cardinal arithmetic. It is convenient to collect these observations, since otherwise their dispersion throughout the several numbers of Part III makes it difficult to see what is their total effect. But although we have placed these observations at the beginning, they are to be read concurrently with the text of Part III, at least with so much of the text as consists of explanations of definitions. The earlier portion of what follows is merely a *résumé* of previous explanations; it is only in the later portions that the application to cardinal arithmetic is made.

I. *General Observations on Types.*

Three different kinds of typical ambiguity are involved in our propositions, concerning:

(1) the functional hierarchy,
(2) the propositional hierarchy,
(3) the extensional hierarchy.

The relevance of these must be separately considered.

We often speak as though the type represented by small Latin letters were not composed of functions. It is, however, compatible with all we have to say that it should be composed of functions. It is to be observed, further, that, given the number of individuals, there is nothing in our axioms to show how many predicative functions of individuals there are, *i.e.* their number is not a function of the number of individuals: we only know that their number $\geqslant 2^{\text{Nc}'\text{Indiv}}$, where "Indiv" stands for the class of individuals.

In practice, we proceed along the extensional hierarchy after the early numbers of the book. If we have started from individuals, the result of this is to exclude functions wholly from our hierarchy; if we have started with functions of a given type, all functions of other types are excluded. Thus a fresh extensional hierarchy, wholly excluding every other, starts from each type of function. When we speak simply of "*the* extensional hierarchy," we mean the one which starts from individuals.

It is to be observed that when we have the assertion of a propositional function, say "$\vdash . \phi x$," the x must be of some definite type, *i.e.* we only assert that ϕx is true whatever x may be within some one type. Thus *e.g.* "$\vdash . x = x$" does not assert more than that this assertion holds for any x of a given type. It is true that symbolically the same assertion holds in other types, but other

types cannot be included under one assertion-sign, because no variable can travel beyond its type.

The process of rendering the types of variables ambiguous is begun in ∗8 and ∗9, where we take the first step in regard to the *propositional* hierarchy. Before ∗8 and ∗9, our variables are *elementary propositions*. These are such as contain no apparent variables. Hence the only functions that occur are matrices, and these only occur through their values. The assumption involved in the transition from Section A to Section B (Part I) is that, given "$\vdash . fp$," where p is an elementary proposition, we may substitute for p "$\phi ! (x, y, z, \ldots)$," where ϕ is any matrix. Thus instead of "$\vdash . fp$," which contained one variable p of a given type, we have "$\vdash . f\{\phi ! (x, y, z, \ldots)\}$," which contains several variables of several types (any finite number of variables and types is possible). This assumption involves some rather difficult points. It is to be remembered that no *value* of ϕ contains ϕ as a constituent, and therefore ϕ is not a constituent of fp even if p is a value of ϕ. Thus we pass, above, from an assertion containing no function as a constituent to one containing one or more functions as constituents. The assertion "$\vdash . fp$" concerns *any* elementary proposition, whereas "$\vdash . f\{\phi ! (x, y, z, \ldots)\}$" concerns *any of a certain set* of elementary propositions, namely any of those that are values of ϕ. Different types of functions give different sorts of ways of picking out elementary propositions.

Having assumed or proved "$\vdash . fp$," where p is elementary and therefore involves no ambiguity of type, we thus assert

$$\vdash . f\{\phi ! (x, y, z, \ldots)\},$$

where the types of the arguments and the number of them are wholly arbitrary, except that they must belong to the functional hierarchy including individuals. (The assumption that propositions are incomplete symbols excludes the possibility that the arguments to ϕ are propositions.) The noteworthy point is that we thus obtain an assertion in which there may be any finite number of variables and the variables have unlimited typical ambiguity, from an assertion containing one variable of a perfectly definite type. All this is presupposed before we embark on the propositional hierarchy.

It should be observed that all elementary propositions are values of predicative functions of one individual, *i.e.* of $\phi ! \hat{x}$, where $\hat{x}$ is individual. Thus we need not *assume* that elementary propositions form a type; we may replace p by "$\phi ! x$" in "$\vdash . fp$." In this way, propositions as variables wholly disappear.

In extending statements concerning elementary propositions so as formally to apply to first-order propositions, we have to assume afresh the primitive proposition ∗1·11 (∗1·1 is never used), *i.e.* given "$\vdash . \phi x$" and "$\vdash . \phi x \supset \psi x$," we have "$\vdash . \psi x$," which is practically ∗9·12. This was asserted in ∗1·11 for any case in which ϕx and ψx are elementary propositions. There was

here already an ambiguity of type, owing to the fact that x need not be an individual, but might be a function of any order. *E.g.* we might use $*1{\cdot}11$ to pass from

$$\text{“}\vdash . \phi ! a\text{” and “}\vdash . \phi ! a \supset \phi ! b\text{” to “}\vdash . \phi ! b,\text{”}$$

where ϕ replaces the x of $*1{\cdot}11$, and $\hat{\phi} ! a$, $\hat{\phi} ! b$ replace $\phi\hat{x}$ and $\psi\hat{x}$. Thus $*1{\cdot}11$, even before its extension in $*9$, already states a fresh primitive proposition for each fresh type of functions considered. The novelty in $*9$ is that we allow ϕ and ψ to contain one apparent variable. This may be of any functional type (including Indiv); thus we get another set of symbolically identical primitive propositions. In passing, as indicated at the end of $*9$, to more than one apparent variable, we introduce a new batch of primitive propositions with each additional apparent variable.

Similar remarks apply to the other primitive propositions of $*9$.

What makes the above process legitimate is that nothing in the treatment of functions of order n *presupposes* functions of higher order. We can deal with each new type of functions as it arises, without having to take account of the fact that there are later types. From symbolic analogy we "see" that the process can be repeated indefinitely. This possibility rests upon two things:

(1) A fresh interpretation of our constants—$\vee$, $\sim$, $!$, $(x)\,.$, $(\exists x)\,.$—at each fresh stage;

(2) A fresh assumption, symbolically unchanged, of the primitive propositions which we found sufficient at an earlier stage—the possibility of avoiding symbolic change being due to the fresh interpretation of our constants.

The above remarks apply to the axiom of reducibility as well as to our other primitive propositions. If, at any stage, we wish to deal with a class defined by a function of the 30,000th type, we shall have to repeat our arguments and assumptions 30,000 times. But there is still no necessity to speak of the hierarchy as a whole, or to suppose that statements can be made about "all types."

We come now to the extensional hierarchy. This starts from some one point in the functional hierarchy. We usually suppose it to start from individuals, but any other starting-point is equally legitimate. Whatever type of functions (including Indiv) we start from, all higher types of functions are excluded from the extensional hierarchy, and also all lower types (if any). Some complications arise here. Suppose we start from Indiv. Then if $\phi ! \hat{z}$ is any predicative function of individuals, $\hat{z}(\phi ! z) = \phi ! \hat{z}$. But if we adopt the theory of $*20$, as opposed to that suggested in the Introduction to the second edition, identity between a function and a class does not have the usual properties of identity; in fact, though every function is identical with some class, and vice versa, the number of functions is likely to be

greater than the number of classes. This is due to the fact that we may have $\hat{z}(\phi ! z) = \psi ! \hat{z} . \hat{z}(\phi ! z) = \chi ! \hat{z}$ without having $\psi ! \hat{z} = \chi ! \hat{z}$.

In the extensional hierarchy, we prove the extension from classes to classes of classes, and so on, without fresh primitive propositions (∗20, ∗21) The primitive propositions involved are those concerning the *functional* hierarchy.

From all these various modes of extension we "see" that whatever *can be proved* for lower types, whether functional or extensional, can also be proved for higher types*. Hence we assume that it is unnecessary to know the types of our variables, though they must always be confined within some one definite type.

Now although everything that can be proved for lower types can be proved for higher types, the converse does not hold. In Vol. I only two propositions occur which can be proved for higher but not for lower types. These are $\exists ! 2$ and $\exists ! 2_r$. These can be proved for any type except that of individuals. It is to be observed that we do *not* state that whatever is *true* for lower types is *true* for higher types, but only that whatever *can be proved* for lower types *can be proved* for higher types. If, for example, $\text{Nc}\text{‘}\text{Indiv} = \nu$, then this proposition is false for any higher type; but this proposition, $\text{Nc}\text{‘}\text{Indiv} = \nu$, is one which cannot be proved logically; in fact, it is only ascertainable by a census, not by logic. Thus among the propositions which can be proved by logic, there are some which can only be proved for higher types, but none which can only be proved for lower types.

The propositions which can be proved in some types but not in others all are or depend upon existence-theorems for cardinals. We can prove

$\exists ! 0$, $\exists ! 1$, universally,
$\exists ! 2$, except for Indiv,
$\exists ! 3$, $\exists ! 4$, except for Indiv, Cl‘Indiv, Rl‘Indiv; and so on.

Exactly similar remarks would apply to the functional hierarchy. In both cases, the possibility of proving these propositions depends upon the axiom of reducibility and the definition of identity. Suppose there is only one individual, x. Then $\hat{y} = x$, $\hat{y} \neq x$ are two different functions, which, by the axiom of reducibility, are equivalent to two different predicative functions. Hence there are at least two predicative functions of x, and at least two classes $\iota\text{‘}x$, Λ_x. This argument fails both for classes and functions if either we deny the axiom of reducibility or we suppose that there may be two different individuals which agree in all their predicates, *i.e.* that the definition of identity is misleading.

The statement that what can be proved for lower types can be proved for higher types requires certain limitations, or rather, a more exact formulation.

* But cf. next page for a more exact statement of this principle.

Taking Indiv as a primitive idea, put

$$\mathrm{Kl} = \mathrm{Cl}\text{‘}\mathrm{Indiv} \quad \mathrm{Df}, \qquad \mathrm{Kl}^2 = \mathrm{Cl}\text{‘}\mathrm{Kl} \quad \mathrm{Df}, \quad \text{etc.}$$

Then consider the proposition $\mathrm{Nc}\text{‘}\mathrm{Kl} = \Lambda$. We can prove

$$\mathrm{Nc}\text{‘}\mathrm{Kl} \cap t\text{‘}\mathrm{Indiv} = \Lambda \,.\, \exists \,!\, \mathrm{Nc}\text{‘}\mathrm{Kl} \cap t\text{‘}\mathrm{Kl} \,.\, \exists \,!\, \mathrm{Nc}\text{‘}\mathrm{Kl} \cap t\text{‘}\mathrm{Kl}^2 \,.\, \text{etc.}$$

Thus $\mathrm{Nc}\text{‘}\mathrm{Kl} = \Lambda$ can be proved in the lowest type in which it is significant, and disproved in any other. The difficulty, however, is avoided if Indiv is replaced by a variable α, and Kl by $\mathrm{Cl}\text{‘}t_0\text{‘}\alpha$. Then we have

$$\mathrm{Nc}\text{‘}\mathrm{Cl}\text{‘}t_0\text{‘}\alpha \cap t\text{‘}\alpha = \Lambda,$$

and this holds whatever the type of α may be. Thus in order that our principle about lower and higher types may be true, it is necessary that any relation there may be between two types occurring in a proposition should be preserved; in other words, when one constant type is *defined* in terms of another (as Kl and Indiv), the definition must be restored before the type is varied, so that when one type is varied, so is the other. With this proviso, our principle about higher and lower types holds.

With the above proviso, the truth of our statement is manifest. For we have shown that the same primitive propositions, symbolically, which hold for the lowest type concerned in our reasoning, hold also for subsequent types; and therefore all our proofs can be repeated symbolically unchanged.

The importance of this lies in the fact that, when we have proved a proposition for the lowest significant type, we "see" that it holds in any other assigned significant type. Hence every proposition which is proved without the mention of any type is to be regarded as proved for the lowest significant type, and extended by analogy to any other significant type.

By exactly similar considerations we "see" that a proposition which can be proved for some type other than the lowest significant type must hold for any type in the direct descent from this. *E.g.* suppose we can prove a proposition (such as $\exists \,!\, 2$) for the type Kl (where $\mathrm{Kl} = \mathrm{Cl}\text{‘}\mathrm{Indiv}$); then merely writing Cl‘Indiv for Kl, we have a proposition which is proved concerning Indiv, namely $\exists \,!\, 2 \cap t\text{‘}\mathrm{Cl}\text{‘}\mathrm{Indiv}$, and here, by what was said before, Indiv may be replaced by any higher type.

Thus given a typically ambiguous relation R, such that, if τ is a type, $R\text{‘}\tau$ is a type (Cl or Rl is such a relation), we "see" that, if we can prove $\phi(R\text{‘}\mathrm{Indiv})$, we can also prove $\phi(R\text{‘}\tau)$, where τ is any type, and ϕ is composed of typically ambiguous symbols. Similarly if we can prove $\phi(\mathrm{Indiv}, R\text{‘}\mathrm{Indiv})$, we can prove $\phi(\tau, R\text{‘}\tau)$, where τ is any type. But we cannot in general prove $\phi(\mathrm{Indiv}, R\text{‘}\tau)$ or $\phi(\tau, R\text{‘}\mathrm{Indiv})$, and these may be in fact untrue. *E.g.* we have $\exists \,!\, \mathrm{Nc}\,(\mathrm{Kl})\text{‘}\mathrm{Indiv} \,.\, \sim\exists \,!\, \mathrm{Nc}\,(\mathrm{Kl})\text{‘}\mathrm{Kl}^2$.

Thus more generally, when a proposition containing several ambiguities can be proved for the types $R\text{‘}\mathrm{Indiv}$, $S\text{‘}\mathrm{Indiv}$, ..., but not for lower types, it

is to be regarded as a function of Indiv, and then it becomes true for *any* type; that is, given

$$\phi\,(R\text{‘Indiv}, S\text{‘Indiv}, \ldots),$$

we shall also have

$$\phi\,(R\text{‘}\tau, S\text{‘}\tau, \ldots),$$

where τ is any type. In this way, *all* demonstrable propositions are in the first instance about Indiv, and when so expressed remain true if any other type is substituted for Indiv.

When a proposition containing typically ambiguous symbols *can be proved* to be true in the lowest significant type, and we can "see" that symbolically the same proof holds in any other assigned type, we say that the proposition has "permanent truth." (We may also say, loosely, that it is "true in all types.") When a proposition containing typically ambiguous symbols *can be proved* to be false in the lowest significant type, and we can "see" that it is false in any other assigned type, we say that it has "permanent falsehood." Any other proposition containing typically ambiguous symbols is said to be "fluctuating," or to have "fluctuating truth-value," as opposed to "permanent truth-value," which belongs to propositions that have either permanent truth or permanent falsehood.

In what follows, ambiguities concerned with the propositional hierarchy will be ignored, since they never lead to fluctuating propositions. Thus disjunction and negation and their derivatives will not receive explicit typical determination, but only such typical determination as results from assigning the types of the other typically ambiguous symbols involved.

It is convenient to call the symbolic form of a propositional function simply a "*symbolic form.*" Thus, if a symbolic form contains symbols of ambiguous type it represents different propositional functions according as the types of its ambiguous symbols are differently adjusted. The adjustment is of course always limited by the necessity for the preservation of meaning. It is evident that the ideas of "permanent truth-value" and "fluctuating truth-value" apply in reality to symbolic forms and not to propositions or propositional functions. Ambiguity of type can only exist in the process of determination of meaning. When the meaning has been assigned to a symbolic form and a propositional function thereby obtained, all ambiguity of type has vanished.

To "assert a symbolic form" is to assert each of the propositional functions arising for the set of possible typical determinations which are somewhere enumerated. We have in fact enumerated a very limited number of types starting from that of individuals, and we "see" that this process can be indefinitely continued by analogy. The form is always asserted so far as the enumeration has arrived; and this is sufficient for all purposes, since it is essentially impossible to use a type which has not been arrived at by successive enumeration from the lower types.

The only difficulties which arise in Cardinal Arithmetic in connection with the ambiguities of type of the symbols are those which enter through the use of the symbol sm, or of the symbol Nc, which is $\overrightarrow{\mathrm{sm}}$. For it may happen that a class in one type has no class similar to it in some lower type (cf. $*102\cdot72\cdot73$). All fallacious reasoning in cardinal or ordinal arithmetic in connection with types, apart from that due to the mere absence of meaning in symbols, is due to this fact—in other words to the fact that in some types $\exists ! \mathrm{Nc}`\alpha$ is true, and in other types $\exists ! \mathrm{Nc}`\alpha$ may not be true. The fallacy consists in neglecting this latter possibility of the failure of $\exists ! \mathrm{Nc}`\alpha$ for a limited number of types, that is, in taking the "fluctuating" form $\exists ! \mathrm{Nc}`\alpha$ as though it possessed a "permanent" truth-value.

A fluctuating form however often possesses what is here termed a "stable" truth-value, which is as important as the permanent truth-value of other forms. For example, anticipating our definitions of elementary arithmetic, consider $2 +_c 3 = 5$. There is no abstract logical proof that there are two individuals; so suppose 2 and 3 refer to classes of individuals, but 5 refers to classes of a high enough type, then with these determinations $2 +_c 3 = 5$ cannot be proved. But $2 +_c 3 = 5$ has a *stable* truth-value, since it can always be proved when all the types are high enough. In this case the fact that our empirical census of individuals (at least of the "relative" individuals of ordinary life) has outrun the capacity of logical proof, makes the fluctuation in the truth-value of the form to be entirely unimportant.

In order to make this idea precise, it is necessary to have a convention as to the order in which the types of symbols in a symbolic form are assigned. The rule we adopt is that the types of the *real variables* are to be first assigned, and then those of the *constant symbols*. The types of the apparent variables, if any, will then be completely determinate.

A symbolic form has a *stable* truth-value if, after any assignment of types to the real variables, types can be assigned to the constant symbols so that the truth-value of the proposition thus obtained is the same as the truth-value of any proposition obtained by modifying it by the assignment of higher types to some or all of the constant symbols. This truth-value is the *stable* truth-value.

II. *Formal Numbers.*

The conventions, which we shall give below as to the assignment of types, practically restrict our interpretation of fluctuating symbolic forms to types in which the forms possess their stable truth-value. The assumption that these truth-values are stable never enters into the reasoning. But we judge a truth-value to be stable when any method of raising the types of the constant symbols by one step leaves it unaltered.

In practice the fluctuation of truth-values only enters into our consideration through a limited number of symbols called "formal numbers."

Formal numbers may be "constant" or "functional."

A *constant* formal number is any constant symbol for which there is a constant α such that, in whatever type the constant symbol is determined, it is, in that type, identical with $\text{Nc}`\alpha$. In other words if $\sigma$ be a constant symbol, then $\sigma$ is a formal number provided that "truth" is the permanent truth-value of $\sigma = \text{Nc}`\alpha$, for some constant α.

The *functional* formal numbers are defined by enumeration; they are

$$\text{Nc}`\alpha,\quad \Sigma\text{Nc}`\kappa,\quad \Pi\text{Nc}`\kappa,\quad \text{sm}``\mu,\quad \mu +_c \nu,\quad \mu -_c \nu,\quad \mu \times_c \nu,\quad \mu^\nu,$$

where in each formal number the symbols α, κ, μ, ν occurring in it are called the arguments of the functional form even when they are complex symbols. The argument of $\text{Nc}`(\alpha+\beta)$ is $\alpha+\beta$, and those of $\mu +_c (\nu +_c \varpi)$ are μ and $\nu +_c \varpi$, and those of $1 +_c 2$ are 1 and 2.

Thus among the constant formal numbers are

$$0,\ 1,\ 2,\ \ldots,\ \aleph_0,\ 1 +_c 2,\ 2 \times_c \aleph_0,\ 2^2.$$

The references which support this statement are

$$*101{\cdot}11{\cdot}21{\cdot}32 \,.\, *123{\cdot}36 \,.\, *110{\cdot}42 \,.\, *113{\cdot}23 \,.\, *116{\cdot}23.$$

Among the functional formal numbers are

$$\text{Nc}`(\alpha+\beta),\quad \mu +_c (\nu +_c \varpi),\quad (\mu +_c \nu) \times_c \varpi,\quad (\mu +_c \nu)^\varpi.$$

It will be observed that *e.g.* $1 +_c 2$ is both a constant and a functional formal number, so that the two classes are not mutually exclusive. In fact they possess an indefinite number of members in common.

All the formal numbers, with the exception of $\text{sm}``\mu$ and $\mu -_c \nu$, are members of NC without any hypothesis [cf. $*100{\cdot}41{\cdot}01{\cdot}52 \,.\, *110{\cdot}42 \,.\, *112{\cdot}101 \,.\, *113{\cdot}23 \,.\, *114{\cdot}1 \,.\, *116{\cdot}23$, note to $*119{\cdot}12$, and $*120{\cdot}411$].

A functional formal number consists of two parts, namely, its argument or arguments, and the constant "form." An argument of a functional formal number may be a complex symbol, and may be constant or variable. Thus $\mu +_c \nu$ is an argument of $(\mu +_c \nu) +_c \rho$, and of $(\mu +_c \nu) \times_c 1$ and of $(\mu +_c \nu)^\rho$; also $2 +_c 3$ is an argument of $(2 +_c 3) \times_c 1$. The constant form is constituted by the other symbols which are constants. Two occurrences of functional formal numbers are only occurrences of the same formal number if the arguments and also the constant forms are identical in symbolism. Thus two occurrences of $\text{Nc}`\alpha$ are occurrences of the same formal number, even if they are determined to be in different types; but $\text{Nc}`\alpha$ and $\text{Nc}`\beta$ are different formal numbers. Also μ^1 and $\mu \times_c 1$ are different formal numbers because their "forms" are different, though the arguments μ and 1 are the same and (in the same type) the entity denoted is the same. Thus the distinction between formal numbers depends on the symbolism and not on the entity denoted, and in considering them it is symbolic analogy and not denotation which is to be taken into account. For example two different

occurrences of the same formal number will not denote the same entity, if in the two occurrences the ambiguity of type is determined differently.

The functional formal numbers are divided into three sets: (i) the *primary* set consisting of the forms $\mathrm{Nc}'\alpha$, $\Sigma\,\mathrm{Nc}'\kappa$, $\Pi\,\mathrm{Nc}'\kappa$, (ii) the argumental set consisting only of $\mathrm{sm}''\mu$, (iii) the arithmetical set consisting of $\mu +_c \nu$, $\mu \times_c \nu$, μ^ν, and $\mu -_c \nu$.

A functional formal number has at most two arguments. But an argument of a functional formal number may itself be a functional formal number, and will accordingly possess either one or two arguments, which in their turn may be functional formal numbers, and so on. The whole set of arguments and of arguments of arguments, thus obtained, is called the set of *components* of the original formal number. Thus μ, ν, ρ and $\mu +_c \nu$ are components of $(\mu +_c \nu) +_c \rho$; and μ, ν and $\mathrm{sm}''\mu$ are components of $\nu +_c \mathrm{sm}''\mu$; and μ, α and $\mathrm{Nc}'\alpha$ are components of $\mu +_c \mathrm{Nc}'\alpha$. The two arguments of $(\mu +_c \nu) +_c \rho$ are $\mu +_c \nu$ and ρ, and those of $\nu +_c \mathrm{sm}''\mu$ are ν and $\mathrm{sm}''\mu$, and those of $\mu +_c \mathrm{Nc}'\alpha$ are μ and $\mathrm{Nc}'\alpha$.

Addition, multiplication, exponentiation, and subtraction will be called the arithmetical operations; and in $\mu +_c \nu$, $\mu \times_c \nu$, μ^ν, $\mu -_c \nu$, μ and ν will each be said to be subjected to these respective operations. The *arithmetical components* of an arithmetical formal number (*i.e.* one belonging to the arithmetical set) consist of those of its components which do not appear in the capacity of components of a component which does not belong to the arithmetical set. Thus $\mu, \nu, \rho, \mu +_c \nu$ are arithmetical components of $(\mu +_c \nu) +_c \rho$; and ν and $\mathrm{sm}''\mu$ are arithmetical components of $\nu +_c \mathrm{sm}''\mu$, but μ is not one; and μ and $\mathrm{Nc}'\alpha$ are arithmetical components of $\mu +_c \mathrm{Nc}'\alpha$, but α is not one; and μ and $\mathrm{sm}''(\nu +_c \rho)$ are arithmetical components of $\mu +_c \mathrm{sm}''(\nu +_c \rho)$, but $\nu +_c \rho$ and ν and ρ are components of $\mathrm{sm}''(\nu +_c \rho)$ and are therefore not *arithmetical* components of $\mu +_c \mathrm{sm}''(\nu +_c \rho)$. Only arithmetical formal numbers possess arithmetical components.

A formal number of the arithmetical set having no components which are formal numbers of the argumental set is called a *pure* arithmetical formal number. For example $\mu +_c (\nu +_c \rho)$ and $\mu +_c \mathrm{Nc}'\alpha$ are pure, but $\mu +_c \mathrm{sm}''(\nu +_c \rho)$ and $\mu +_c \mathrm{sm}''\mathrm{Nc}'\alpha$ are not pure.

There are many types involved in the consideration of a formal number. For example, in $\mathrm{Nc}'\alpha$ there is the type of $\mathrm{Nc}'\alpha$ and of α; in $\mu +_c \nu$ there is the type of $\mu +_c \nu$, the type of μ, and the type of ν; and so on for more complex formal numbers. The type of a formal number as a whole in any occurrence is called its *actual type*. This is the type of the entity which it then represents.

The other types involved in a formal number in any occurrence are called its subordinate types.

The actual types are not indicated in the symbolism for the various formal numbers as stated above. They can be indicated relatively to the type of the

variable ξ by writing $\text{Nc}(\xi)\text{‘}\alpha$, $\text{sm}_\xi\text{‘‘}\mu$, $(\mu +_c \nu)_\xi$, $(\mu \times_c \nu)_\xi$, $(\mu^\nu)_\xi$, $(\mu -_c \nu)_\xi$, by the notation of $*65$. Even when the actual type of a complex formal number, such as $\mu +_c (\nu +_c \varpi)$, is settled—so for instance that we have $\{\mu +_c (\nu +_c \varpi)\}_\xi$—the meaning of the symbol is not completely determined, for the type of $\nu +_c \varpi$ remains ambiguous. It follows, however, from

$$*100{\cdot}511 \,.\, *110{\cdot}23 \,.\, *113{\cdot}26 \,.\, *119{\cdot}61{\cdot}62,$$

that the subordinate types make no difference to the value of a formal number, so long as the components are not null.

We can therefore make a formal number definite as soon as its actual type is definite by securing that its components are not null. This is done by the convention II T (below) combined with the definitions

$$*110{\cdot}03{\cdot}04 \,.\, *113{\cdot}04{\cdot}05 \,.\, *116{\cdot}03{\cdot}04.$$

When the subordinate types are adjusted in accordance with these definitions and conventions, they will be said to be *normally adjusted.*

But in order to state this convention II T we require a definition of what is here called the *adequacy* of the actual type of a formal number. The general idea of adequacy is simple enough, namely that, given the subordinate types of σ, the actual type of σ should be high enough to enable us logically to prove $\exists ! \sigma$ when such a proof is possible for types which are not too low. For example, all types except the lowest for which it has meaning are adequate for the constant formal number 2. It is rather difficult however to state the meaning of adequacy with precision in a manner adapted to all formal numbers. Fortunately the definition of the lowest type which corresponds to this general idea of adequacy is not important for our purposes. It will be sufficient to define as adequate some types which certainly do have the property in question.

The method of definition which we adopt is to replace the formal number σ by another one σ' so related to σ that with the same actual type for both we can prove $\exists ! \sigma' \,.\, \supset \,.\, \exists ! \sigma$, whenever σ is not equal to Λ in all types. If σ be functional, we need only consider its argument, or its two arguments, and can dismiss from consideration the other components; then we replace these arguments by others so that the σ' has the required property. Thus:

(i) The actual types of $\text{Nc‘}\alpha$, $\Sigma\text{Nc‘}\kappa$, $\Pi\text{Nc‘}\kappa$, and $\text{sm‘‘}\mu$ are adequate when we can logically prove

$$\exists ! \text{Nc‘}t_0\text{‘}\alpha, \;\; \exists ! \Sigma\text{Nc‘}t_0\text{‘}\kappa, \;\; \exists ! \Pi\text{Nc‘}t_0\text{‘}\kappa, \text{ and } \exists ! \text{sm‘‘}t_0\text{‘}\mu;$$

(ii) The actual types of $\mu +_c \nu$, $\mu -_c \nu$, $\mu \times_c \nu$, and μ^ν are adequate when we can logically prove

$$\exists ! \text{N}_0\text{c‘}t_1\text{‘}\mu +_c \text{N}_0\text{c‘}t_1\text{‘}\nu, \quad \exists ! \text{N}_0\text{c‘}t_1\text{‘}\mu -_c 0 \cap t_0\text{‘}\nu,$$
$$\exists ! \text{N}_0\text{c‘}t_1\text{‘}\mu \times_c \text{N}_0\text{c‘}t_1\text{‘}\nu, \text{ and } \exists ! \text{N}_0\text{c‘}t_1\text{‘}\mu^{\text{N}_0\text{c‘}t_1\text{‘}\nu}.$$

It will be noticed that $t_0\text{‘}\alpha$, $t_0\text{‘}\kappa$, and $t_0\text{‘}\mu$ are the greatest classes of the same type as α, κ, and μ respectively, and that $\text{N}_0\text{c‘}t_1\text{‘}\mu$ and $\text{N}_0\text{c‘}t_1\text{‘}\nu$ are the greatest

cardinal numbers of the same type as μ and ν respectively. These definitions hold even when any of α, κ, μ, ν are complex symbols.

The remaining formal numbers which are not functional must certainly be constant. The difficulty which arises here is that if σ be such a formal number and $\aleph_0$ occurs in its symbolism, we have no logical method of deciding as to the truth or falsehood of $\exists ! \aleph_0$ in any type. But we replace $\aleph_0$ by $N_0c`t_1`\aleph_0$ which is the greatest existent cardinal of the same type as $\aleph_0$ in that occurrence. Thus:

(iii) If σ be a formal number which is not functional, an adequate actual type of σ is one for which we can logically prove $\exists ! \sigma'$, where σ' is derived from σ by replacing any occurrence of $\aleph_0$ in σ by $N_0c`t_1`\aleph_0$. Accordingly if $\aleph_0$ does not occur in σ, an adequate type is any actual type for which we can logically prove $\exists ! \sigma$.

In the case of members of the primary and argumental groups we have substituted the V of the appropriate type in the place of each variable. When the actual type is adequate we have

$$(\alpha) . \exists ! Nc`\alpha, \quad (\kappa) . \exists ! \Sigma Nc`\kappa, \quad (\kappa) . \exists ! \Pi Nc`\kappa, \quad (\mu) . \exists ! sm``\mu.$$

In the case of members of the arithmetical group (except in the case of $\mu -_c \nu$), we have substituted for each argument the largest cardinal number which can be obtained in the type of that argument, namely the $N_0c`V$ for the V of the appropriate type. Accordingly we are sure (except in the case of $\mu -_c \nu$) that for all other values of the arguments which are existent cardinal numbers the formal number is not null.

It will be noticed that normal adjustment only concerns the subordinate types. For example $*110{\cdot}03$ secures that in $Nc`\alpha +_c \mu$ the actual type of $Nc`\alpha$ is adequate, and $*110{\cdot}23$ shows that any adequate actual type of $Nc`\alpha$ will do. But nothing is said about the actual type of $Nc`\alpha +_c \mu$. We make the following definition: When the subordinate types of a formal number are normally adjusted, and the actual type is adequate, the types of the formal number are said to be *arithmetically* adjusted.

We notice that for the primary set, the arithmetical adjustment of types means the same thing as the adequate adjustment of the actual type. Also if the arguments of a formal number of the arithmetical set are simple symbols, the two ideas come to the same thing.

In the case of variable formal numbers of the primary set, it follows from $*117{\cdot}22{\cdot}32$ that when their types are arithmetically adjusted they are not equal to Λ for any values of their variables.

Also in the case of those variable formal numbers which are of the pure arithmetical set (excluding $\mu -_c \nu$) it follows from $*100{\cdot}4{\cdot}52{\cdot}42 . *113{\cdot}23 . *116{\cdot}23$ that, working from the ultimate components reached by successive analysis upwards, for all values of such ultimate components which are members

of $NC - \iota`\Lambda$ they can be reduced to the case of the formal numbers of the primary group; and that therefore they are not equal to Λ when their types are arithmetically adjusted. For example in $\mu +_c \{\nu +_c (\rho +_c \sigma)\}$, μ, ν, ρ, σ are these ultimate components; let them be existent cardinal numbers. Hence when the types are arithmetically adjusted, the actual type of $\rho +_c \sigma$ is adequate and $\rho +_c \sigma$ is an existent cardinal; we can therefore substitute $N_0c`\alpha$ for it. By the same reasoning we can substitute $N_0c`\beta$ for $\nu +_c N_0c`\alpha$, and again $N_0c`\gamma$ for $\mu +_c N_0c`\beta$.

A definite standard arithmetical adjustment of types for any formal number can always be found by making every use of sm, whether explicit or concealed in Nc or in some other symbol, to be homogeneous. Proofs which apply to any arithmetical adjustment of types start by dealing with this standard type, and then by the use of *104·21 . *106·21·211·212·213 the extension is made to the adjacent higher classical and relational types. We then "see" that by the analogy of symbolism this extension can always be formally proved at each stage, so that we are dealing with the stable truth-value. For some constant formal numbers a lower existential type can be found than that indicated by this method.

III. *Classification of Occurrences of Formal Numbers.*

A symbolic form of any of the kinds [cf. *117·01·04·05·06]

$$\mu > \nu, \quad \mu < \nu, \quad \mu \geqslant \nu, \quad \mu \leqslant \nu,$$

is called an *arithmetical inequality*.

These forms only arise when we are comparing cardinal numbers in respect to the relation of being "greater than" or "less than." It might seem natural to include equations among these arithmetical inequalities. Their use however, even as between cardinal numbers, is not so exclusively arithmetical, and it is convenient to consider them separately under another heading during our preliminary investigations.

In the arithmetical inequalities as above written, μ and ν, or any symbols replacing μ and ν, are called the *opposed sides* of the inequality, and either of μ or ν is called a *side* of the inequality.

Symbolic forms of the kinds $\sigma = \kappa$ and $\sigma \neq \kappa$, where either σ or κ is a formal number, will be called *equations* and *inequations* respectively; and σ and κ are called the *opposed sides* of the equation or inequation, and either of them is simply a *side* of the equation or inequation.

When we reach the exclusively arithmetical point of view, it will be convenient to put together equations, inequations and arithmetical inequalities as one sort of symbolic form. Their separation here is for the sake of investigations into the exceptions due to the failure of existence theorems in low types. It is unnecessary to consider arithmetical inequalities in this connection.

The ways in which a symbol σ can occur in a symbolic form are named as follows:

The occurrence of σ in $\mathrm{sm}``\sigma$ is called an *argumental* occurrence,

The occurrence of σ as an argument of an arithmetical formal number (which may be a component of another formal number) or as one side of an arithmetical inequality is called an *arithmetical* occurrence,

The occurrence of σ as one side of an equation is called an *equational* occurrence,

The occurrence of σ in "$\xi \epsilon \sigma$" is called an *attributive* occurrence,

Any other occurrence of σ is called a *logical* occurrence, so also is $\sigma = \Lambda$.

It is obvious that a pair of opposed sides of an equation or inequation must be of the same type. Furthermore, if σ be a formal number, and **∗20·18** is applied so as to give

$$\vdash :. \sigma = \kappa . \supset : f(\sigma) . \equiv . f(\kappa),$$

the equational occurrence of σ must be of the same type as its occurrence in $f(\sigma)$, otherwise the inference is fallacious. Accordingly substitution in arithmetical formulae can only be undertaken when the conventions as to the relations of ambiguous types secure this identity. This question is considered later in this prefatory statement, and the result appears in the text as ∗118·01.

At this point some examples will be useful; they will also be referred to subsequently in connection with the conventions limiting ambiguities of type.

∗100·35. $\vdash :. \exists ! \mathrm{Nc}`\alpha . \vee . \exists ! \mathrm{Nc}`\beta : \supset :$

$$\mathrm{Nc}`\alpha = \mathrm{Nc}`\beta . \equiv . \alpha \epsilon \mathrm{Nc}`\beta . \equiv . \beta \epsilon \mathrm{Nc}`\alpha . \equiv . \alpha \,\mathrm{sm}\, \beta$$

Here the formal numbers are $\mathrm{Nc}`\alpha$ and $\mathrm{Nc}`\beta$, each of which has three occurrences. The first occurrence of $\mathrm{Nc}`\alpha$ is logical, its second is equational, and its third is attributive.

∗100·42 (in the demonstration).

$$\vdash : \mu, \nu \epsilon \mathrm{NC} . \exists ! \mu \cap \nu . \supset . (\exists \alpha, \beta) . \mu = \mathrm{Nc}`\alpha . \nu = \mathrm{Nc}`\beta . \mathrm{Nc}`\alpha = \mathrm{Nc}`\beta$$

Here $\mathrm{Nc}`\alpha$ and $\mathrm{Nc}`\beta$ are the only formal numbers, and all their occurrences are equational.

∗100·44 (in the demonstration).

$$\vdash : \mu \epsilon \mathrm{NC} . \exists ! \mathrm{Nc}`\alpha . \alpha \epsilon \mu . \supset . (\exists \beta) . \mu = \mathrm{Nc}`\beta . \mathrm{Nc}`\alpha = \mathrm{Nc}`\beta$$

Here $\mathrm{Nc}`\alpha$ and $\mathrm{Nc}`\beta$ are the only formal numbers; the first occurrence of $\mathrm{Nc}`\alpha$ is logical, its second is equational; both the occurrences of $\mathrm{Nc}`\beta$ are equational.

∗100·511. $\vdash : \exists ! \mathrm{Nc}`\beta . \supset . \mathrm{sm}``\mathrm{Nc}`\beta = \mathrm{Nc}`\beta$

Here the formal numbers are $\mathrm{Nc}`\beta$ and $\mathrm{sm}``\mathrm{Nc}`\beta$. The first occurrence of $\mathrm{Nc}`\beta$ is logical, the second is argumental, the third is equational; the only occurrence of $\mathrm{sm}``\mathrm{Nc}`\beta$ is equational.

∗100·521. $\vdash : \mu \in \mathrm{NC} \,.\, \exists\,!\, \mathrm{sm}``\mu \,.\, \supset \,.\, \mathrm{sm}``\mathrm{sm}``\mu = \mu$

Here sm$``\mu$ and sm$``$sm$``\mu$ are the only formal numbers; sm$``\mu$ has two occurrences, the first logical, the second argumental; sm$``$sm$``\mu$ has one occurrence, which is equational.

∗101·28 (in the demonstration).

$$\vdash : \gamma \in \mathrm{sm}``1 \,.\, \equiv \,.\, (\exists \alpha) \,.\, \alpha \in 1 \,.\, \gamma \,\mathrm{sm}\, \alpha$$

Here the formal numbers are 1 and sm$``$1. The first occurrence of 1 is argumental, the second is attributive; the occurrence of sm$``$1 is attributive.

∗101·38. $\vdash : \exists\,!\, 2 \,.\, \supset \,.\, s`\mathrm{Cl}``2 = 0 \cup 1 \cup 2$

Here the formal numbers are 0, 1, and 2, and their occurrences are all logical.

∗110·54. $\vdash \,.\, (\mathrm{Nc}`\alpha +_c \mathrm{Nc}`\beta) +_c \mathrm{Nc}`\gamma = \mathrm{Nc}`(\alpha + \beta + \gamma)$

Here the formal numbers are

$\mathrm{Nc}`\alpha$, $\mathrm{Nc}`\beta$, $\mathrm{Nc}`\gamma$, $\mathrm{Nc}`(\alpha + \beta + \gamma)$, $\mathrm{Nc}`\alpha +_c \mathrm{Nc}`\beta$, $(\mathrm{Nc}`\alpha +_c \mathrm{Nc}`\beta) +_c \mathrm{Nc}`\gamma$.

The occurrence of $\mathrm{Nc}`(\alpha + \beta + \gamma)$ and that of $(\mathrm{Nc}`\alpha +_c \mathrm{Nc}`\beta) +_c \mathrm{Nc}`\gamma$ are both equational, and they must be of the same type since they are opposed sides of the same equation. The occurrences of the other formal numbers are as arithmetical components of a more complex arithmetical formal number and are therefore arithmetical.

∗116·63. $\vdash \,.\, \mu^{\nu \times_c \varpi} = (\mu^\nu)^\varpi$

The formal numbers are $\nu \times_c \varpi$, μ^ν, $\mu^{\nu \times_c \varpi}$, and $(\mu^\nu)^\varpi$. Each formal number occurs once only. The occurrences of $\nu \times_c \varpi$ and μ^ν are arithmetical, and those of the other two are equational.

∗117·108. $\vdash :. \mathrm{Nc}`\alpha \geqslant \mathrm{Nc}`\beta \,.\, \equiv : \mathrm{Nc}`\alpha > \mathrm{Nc}`\beta \,.\, \mathrm{v} \,.\, \mathrm{Nc}`\alpha = \mathrm{Nc}`\beta$

The formal numbers are $\mathrm{Nc}`\alpha$ and $\mathrm{Nc}`\beta$, each with three occurrences. The first two occurrences of each formal number are arithmetical, the last occurrence of each is equational.

∗120·53 (in the demonstration).

$$\vdash : \beta = \gamma +_c \delta \,.\, \exists\,!\, \beta \,.\, \supset \,.\, \alpha^\beta = \alpha^\gamma \times_c \alpha^\delta$$

Here the formal numbers are $\gamma +_c \delta$, α^β, α^γ, α^δ, $\alpha^\gamma \times_c \alpha^\delta$. Each formal number has one occurrence. Those of $\gamma +_c \delta$, α^β and $\alpha^\gamma \times_c \alpha^\delta$ are equational, and those of α^γ and α^δ are arithmetical.

∗120·53 (in the demonstration).

$$\vdash : \alpha^\beta = \alpha^\gamma \,.\, \beta = \gamma +_c \delta \,.\, \exists\,!\, \alpha^\beta \,.\, \supset \,.\, \alpha^\gamma = \alpha^\gamma \times_c \alpha^\delta$$

Here the formal numbers are α^β, α^γ, α^δ, $\alpha^\gamma \times_c \alpha^\delta$, $\gamma +_c \delta$. The first occurrence of α^β is equational, its second occurrence is logical; the first two occurrences of α^γ are equational, its third occurrence is arithmetical; the only occurrence of α^δ is arithmetical; the only occurrences of $\alpha^\gamma \times_c \alpha^\delta$ and of $\gamma +_c \delta$ are equational.

IV. *The Conventions* IT *and* IIT.

Two occurrences of a formal number with the same actual type are said to be *bound* to each other.

The choice of types for formal numbers, when they are not made definite in terms of variables by the notation of ∗65, is limited by the following conventions, which enable us to dispense largely with the elaboration produced by the definition of types.

IT. *All logical occurrences of the same formal number are in the same type; argumental occurrences are bound to logical and attributive occurrences; and, if there are no argumental occurrences, equational occurrences are bound to logical occurrences.*

This rule only applies, so far as meaning permits, to those types which remain ambiguous after the assignment of types to the real variables.

It will be noticed that if there are no argumental or logical occurrences of a formal number, IT does not in any way apply to the assignment of types to the occurrences in the form of that formal number.

The identification of types in argumental and attributive occurrences by IT is rendered necessary to secure the use of the equivalence

$$\gamma \in \mathrm{sm}``\sigma \,.\equiv .\, (\exists \alpha) \,.\, \alpha \in \sigma \,.\, \gamma \,\mathrm{sm}\, \alpha,$$

where σ is a formal number. Without the convention, this application of ∗37·1 would be fallacious. The only one of our examples to which this part of the convention applies is ∗101·28 (demonstration), where it secures that the two occurrences of 1 are in the same type. It is relevant however to the symbolism in the demonstration of ∗100·521.

It will be found in practice that this convention relates the types of occurrences in the same way as would naturally be done by anyone who was not thinking of the convention at all. To see how the convention works, we will run through the examples which have already been given above.

In ∗100·35, IT directs the logical and equational occurrences of $\mathrm{Nc}`\alpha$ to be in the same type, and similarly for $\mathrm{Nc}`\beta$. Also "meaning" secures that the equational types of $\mathrm{Nc}`\alpha$ and $\mathrm{Nc}`\beta$ are the same. Thus these four occurrences are all in one type, which has no necessary relation to the types of the attributive occurrences of $\mathrm{Nc}`\alpha$ and $\mathrm{Nc}`\beta$. Thus, using the notation of ∗65·04 to secure typical definiteness, ∗100·35 is to mean

$$\vdash :. \exists ! \,\mathrm{Nc}\,(\xi)`\alpha \,.\vee .\, \exists ! \,\mathrm{Nc}\,(\xi)`\beta : \supset :$$
$$\mathrm{Nc}\,(\xi)`\alpha = \mathrm{Nc}\,(\xi)`\beta \,.\equiv .\, \alpha \in \mathrm{Nc}\,(\alpha)`\beta \,.\equiv .\, \beta \in \mathrm{Nc}\,(\beta)`\alpha \,.\equiv .\, \alpha \,\mathrm{sm}\, \beta.$$

The types of these attributive occurrences are settled by the necessity of 'meaning."

In ∗100·42 (demonstration), since all the occurrences of formal numbers are equational, IT produces no limitation of types.

In $*100\cdot44$ (demonstration), IT secures that the two occurrences of $\text{Nc}`\alpha$ are in the same type. Also we notice that the first occurrence of $\text{Nc}`\beta$ is really (cf. $*65\cdot04$) $\text{Nc}\,(\alpha)`\beta$, since "$\alpha \epsilon \mu$" occurs, and thus "meaning" requires this relation of types, and the second occurrence of $\text{Nc}`\beta$ is in the type of the occurrences of $\text{Nc}`\alpha$.

In $*100\cdot511$, IT directs that the logical and argumental occurrences are to have the same type. In $*100\cdot521$, IT directs that the two occurrences of $\text{sm}``\mu$ are to have the same type. In $*101\cdot28$ both occurrences of 1 are to be in the same type. In $*101\cdot38$, IT directs that all the occurrences of 2 are to have the same type.

The convention IT in no way limits the types in $*110\cdot54$, nor in $*116\cdot63$, nor in $*117\cdot108$.

In the first example from $*120\cdot53$ (in the demonstration) convention IT has no application.

In the second example from $*120\cdot53$ (in the demonstration) convention IT directs that the two occurrences of α^β shall be in the same type; and the necessity of "meaning" secures that the first occurrence of α^γ shall also be in this type. The same necessity secures that $\gamma +_0 \delta$ shall be in the same type as β; and it also secures that in "$\alpha^\gamma = \alpha^\gamma \times_0 \alpha^\delta$" the first occurrence of α^γ and that of $\alpha^\gamma \times_0 \alpha^\delta$ shall have a common type, which is otherwise unfettered; also nothing has been decided as to the types of α^γ and α^δ in $\alpha^\gamma \times_0 \alpha^\delta$.

We now come to conventions embodying the outcome of arithmetical ideas. The term "arithmetical" is here used to denote investigations in which the interest lies in the comparison of formal numbers in respect to equality or inequality, excluding the exceptional cases—whenever the cases are exceptional—due to the failure of existence in low types. The thorough-going arithmetical point of view, which we adopt later in the investigation on Ratio and Quantity and also in this volume in $*117$ and $*126$ and some earlier propositions, would sweep aside as uninteresting all investigation of the exact ways in which the failure of existence theorems is relevant to the truth of propositions, thus concentrating attention exclusively on stable truth-values. But the logical investigation has its own intrinsic interest among the principles of the subject. It is obvious however that it should be restrained to a consideration of the theorems of purely logical interest. In practice this extrusion of uninteresting cases of the failure of arithmetical theorems, even amid the logical investigations of the first part of this volume, is effected by securing that *all arithmetical occurrences of formal numbers have their actual types adequate.*

As far as formal numbers of the primary group, *i.e.* $\text{Nc}`\alpha$, $\Sigma\text{Nc}`\kappa$, $\Pi\text{Nc}`\kappa$, are concerned, the arithmetical adjustment of types is secured formally in the symbolism by the definitions $*110\cdot03\cdot04$ for addition, and $*113\cdot04\cdot05$ for

multiplication, and $*116\cdot03\cdot04$ for exponentiation, and $*117\cdot02\cdot03$ for arithmetical inequalities, and $*119\cdot02\cdot03$ for subtraction.

We save the symbolic elaboration which would arise from the extension of similar definitions to other formal numbers by the following convention:

IIT. *Whenever a formal number σ occurs, so that, if it were replaced by* $\text{Nc}`\alpha$, *the actual type of* $\text{Nc}`\alpha$ *would by definition have to be adequate, then the actual type of σ is also to be adequate.*

For example in $\mu +_c (\nu +_c \varpi)$, if $\nu +_c \varpi$ were replaced by $\text{Nc}`\alpha$, then by $*110\cdot04$ the actual type of $\text{Nc}`\dot{\alpha}$ is adequate. Hence by IIT the actual type of $\nu +_c \varpi$ is to be adequate: accordingly so long as ν and ϖ are simple variables and members of $\text{NC} - \iota`\Lambda$, we can always assume $\exists ! (\nu +_c \varpi)$ for the type of the occurrence of $\nu +_c \varpi$ in $\mu +_c (\nu +_c \varpi)$.

It is essential to notice that so long as the argument of an argumental formal number, or the arguments of an arithmetical formal number, are adjusted arithmetically, the exact types chosen make no difference. This follows for argumental formal numbers from $*102\cdot862\cdot87\cdot88$, for addition from $*110\cdot25$, for multiplication from $*113\cdot26$, for exponentiation from $*116\cdot26$, for subtraction from $*119\cdot61\cdot62$. Thus (remembering also $*100\cdot511$) in any definite type a formal number has one definite meaning provided that any subordinate formal number which occurs in its symbolism is determined existentially. The convention IIT directs us always to take this definite meaning for any pure arithmetical formal number.

The convention does not determine completely the meaning of an arithmetical formal number which is not pure. For example, $\mu +_c (\nu +_c \rho)$ is a pure arithmetical formal number when μ, ν, ρ are determined in type; and convention IIT directs that the type of $(\nu +_c \rho)$ is to be adequate. But $\mu +_c \text{sm}``(\nu +_c \rho)$ is an arithmetical formal number which is not pure, and convention IIT directs that the type of the domain of sm is to be adequate, but does not affect the type of $\nu +_c \rho$. Thus it is easy to see that IIT secures the adequacy of the actual types of all *arithmetical* components of any arithmetical formal numbers which occur, but does not affect the actual type of a formal number which occurs as the argument of an argumental formal number. But in this case convention IT will bind the actual type of this occurrence of the argument to any logical or attributive occurrence of the same formal number. For example, if $\exists ! \nu +_c \rho$ and $\mu +_c \text{sm}``(\nu +_c \rho)$ occur in the same form, then these two occurrences of $\nu +_c \rho$ must have the same actual type. In practice argumental formal numbers are useful as components of arithmetical formal numbers for the very purpose of avoiding the automatic adjustment of types directed by IIT.

The meaning of IIT is best explained by examples. Among our previous examples we need only consider those in which arithmetical formal numbers occur.

In $*110{\cdot}54$ the convention or definitions direct us to determine the types of $\text{Nc}`\alpha$ and $\text{Nc}`\beta$ adequately when forming $\text{Nc}`\alpha +_c \text{Nc}`\beta$, also to determine $\text{Nc}`\alpha +_c \text{Nc}`\beta$ and $\text{Nc}`\gamma$ adequately when forming $(\text{Nc}`\alpha +_c \text{Nc}`\beta) +_c \text{Nc}`\gamma$. The convention does not apply to the types of $(\text{Nc}`\alpha +_c \text{Nc}`\beta) +_c \text{Nc}`\gamma$ and $\text{Nc}`(\alpha + \beta + \gamma)$. These types must be identical in order to secure meaning.

In $*116{\cdot}63$ the convention directs us to adjust the types of $\nu \times_c \varpi$ and μ^ν adequately; it does not affect the types of $\mu^{\nu \times_c \varpi}$ and $(\mu^\nu)^\varpi$, which must be identical to secure meaning. If we replace μ, ν, ϖ by formal numbers, by 2, $\aleph_0$, and 1 for example, we get "$\vdash . 2^{\aleph_0 \times_c 1} = (2^{\aleph_0})^1$." The convention now directs that 1 is to be determined adequately. It so happens that any type is adequate for it, since $\exists ! 1$ can be proved in any type. Then adequate types for $\aleph_0 \times_c 1$ and $2^{\aleph_0}$ are types for which we can prove $\exists ! (\text{N}_0\text{c}`t_1`\aleph_0) \times_c 1$ and $\exists ! 2^{\text{N}_0\text{c}`t_1`\aleph_0}$. Thus if τ is the type of $\aleph_0$ in both cases, an adequate type for $\aleph_0 \times_c 1$ is τ, and for $2^{\aleph_0}$ is $\text{Cl}`\tau$.

In $*117{\cdot}108$ we find arithmetical occurrences in arithmetical inequalities. Thus IIT directs us to take the first two occurrences of $\text{Nc}`\alpha$ and the first two of $\text{Nc}`\beta$ with adequate actual types. The type of $\text{Nc}`\alpha$ and $\text{Nc}`\beta$ in $\text{Nc}`\alpha = \text{Nc}`\beta$ is not affected by it. It is evident that the conventions IT, IIT are not sufficient to secure the truth of this proposition as thus symbolized. It is essential that in the equation the type be adjusted adequately for both formal numbers. In fact the general arithmetical convention, that types of equational as well as of arithmetical occurrences are adjusted arithmetically, is here used.

V. *Some Important Principles.*

Principle of Arithmetical Substitution. In $*120{\cdot}53$, the application of IIT needs a consideration of the whole question of arithmetical substitution. Consider the first of the two examples. We have

$$\vdash : \beta = \gamma +_c \delta . \exists ! \beta . \supset . \alpha^\beta = \alpha^\gamma \times_c \alpha^\delta.$$

It is obvious that unless we can pass with practical immediateness from "$\beta = \gamma +_c \delta . \alpha^\beta = \alpha^\beta$" to "$\alpha^\beta = \alpha^{\gamma +_c \delta}$" by $*20{\cdot}18$, arithmetic is made practically impossible by the theory of types. But a difficulty arises from the application of IIT. Suppose we assign the types of our real variables first. Then the types of α, β, γ, δ can be arbitrarily assigned, and there is no necessary connection between them which arises from the preservation of meaning. Thus β may be in a type which is not an adequate type for $\gamma +_c \delta$. Assume that this is the case. But the equational use of $\gamma +_c \delta$ is in the same type as β, and by IIT the arithmetical use of $\gamma +_c \delta$ in $\alpha^{\gamma +_c \delta}$ is in an adequate type. Thus, on the face of it, the reasoning, appealing to $*20{\cdot}18$, by which the substitution was justified, is fallacious; for the two occurrences of $\gamma +_c \delta$ in fact mean different things.

In order to generalize our solution of this difficulty it is convenient to define the term "arithmetical equation." An *arithmetical equation* is an

equation between purely arithmetical formal numbers whose actual types are both determined adequately. Then it is evident that from "$\sigma = \tau . f(\tau)$," where σ and τ are formal numbers and τ occurs arithmetically in $f(\tau)$, we cannot infer $f(\sigma)$ unless the equation $\sigma = \tau$ is arithmetical. For otherwise the τ in the equation cannot be identified with the τ in $f(\tau)$.

When we have "$\beta = \tau . f(\tau)$," where τ is a formal number and β is a number in a definite type, and wish to pass to "$f(\beta)$," or "$\beta = \tau . f(\beta)$" and wish to pass to "$f(\tau)$," the occurrence of τ in $f(\tau)$ being arithmetical, the type of β may not be an adequate type for τ. Accordingly the τ in "$\beta = \tau$" cannot be identified with the τ in $f(\tau)$. The type of the τ in the equation ought to be freed from dependence on that of β. Accordingly the transition is only legitimate when we can write instead

$$\text{"}\beta +_c 0 = \tau . f(\tau)\text{" or "}\beta +_c 0 = \tau . f(\beta)\text{,"}$$

where in both cases the equation is arithmetical. For now all the symbols are subject to the same rules.

If this modification can be made without altering the truth-value of the asserted propositions, the substitution is legitimate, otherwise it is not.

It is obvious that in the above our immediate passage is to or from $f(\beta +_c 0)$. But it is easy to see that, the occurrence of $\beta +_c 0$ being arithmetical, we always have

$$f(\beta) . \equiv . f(\beta +_c 0).$$

In order to prove this, we have only to prove

$$\alpha +_c (\beta +_c 0) = \alpha +_c \beta,$$
$$\alpha \times_c (\beta +_c 0) = \alpha \times_c \beta,$$
$$(\alpha +_c 0)^\beta = \alpha^\beta,$$
$$\alpha^{\beta +_c 0} = \alpha^\beta,$$

and $$\alpha > \beta +_c 0 . \equiv . \alpha > \beta . \equiv . \alpha +_c 0 > \beta.$$

The demonstration of the first of these propositions runs as follows:

$\vdash . *110\cdot4 . \supset \vdash :. \beta \sim \epsilon \mathrm{NC} . \mathrm{v} . \beta = \Lambda : \supset . \beta +_c 0 = \Lambda . \alpha +_c \beta = \Lambda .$

$[*110\cdot4] \qquad \supset . \alpha +_c (\beta +_c 0) = \Lambda = \alpha +_c \beta$ (1)

$\vdash . *110\cdot4 . \supset \vdash :. \alpha \sim \epsilon \mathrm{NC} . \mathrm{v} . \alpha = \Lambda : \supset . \alpha +_c (\beta +_c 0) = \Lambda = \alpha +_c \beta$ (2)

$\vdash . *110\cdot6 . \supset \vdash : \alpha, \beta \epsilon \mathrm{NC} - \iota`\Lambda . \supset . \alpha +_c (\beta +_c 0) = \alpha +_c \mathrm{sm}``\beta$

$\qquad = \alpha +_c \beta$ (3)

$\vdash . (1) . (2) . (3) . \supset \vdash : \alpha +_c (\beta +_c 0) = \alpha +_c \beta$

In the above demonstration the step to (3) is legitimate since by the hypothesis β is a determination of $\mathrm{sm}``\beta$ in an adequate type.

Similar proofs hold for the other propositions, using $*113\cdot204$ and $*116\cdot204$ and $*117\cdot12$ and $*103\cdot13$.

We must also consider the circumstances under which we can pass from "$\beta = \tau$" to "$\beta +_c 0 = \tau$," where the latter equation is arithmetical. In other

words, using $*65{\cdot}01$ we require the hypothesis necessary for

$$\exists ! \tau_\eta . \beta = \tau_\xi . \supset . \beta +_c 0 = \tau_\eta .$$

We have

$$\vdash . *20{\cdot}18 . \quad \supset \vdash : \beta = \tau_\xi . \supset . \beta +_c 0 = \tau_\xi +_c 0 \qquad (1)$$

$$\vdash . *110{\cdot}35 . \supset \vdash : \exists ! \tau_\xi . \exists ! \tau_\eta . \supset . \tau_\xi +_c 0 = \tau_\eta +_c 0 \qquad (2)$$

$$\vdash . (1) . (2) . \supset \vdash :. \exists ! \tau_\xi . \exists ! \tau_\eta . \supset : \beta = \tau_\xi . \supset . \beta +_c 0 = \tau_\eta +_c 0 \quad (3)$$

$$\vdash . (3) . \quad \supset \vdash :. \exists ! \beta . \exists ! \tau_\eta . \supset : \beta = \tau_\xi . \supset . \beta +_c 0 = \tau_\eta +_c 0 \quad (4)$$

Now in (4) the occurrences of $\beta +_c 0$ and $\tau_\eta +_c 0$, which are in the same type, may be chosen to be in any type we like. Hence we deduce

$$\vdash . (4) . *110{\cdot}6 . \supset \vdash :. \exists ! \beta . \exists ! \tau_\eta . \supset : \beta = \tau_\xi . \supset . (\beta +_c 0)_\zeta = \mathrm{sm}_\zeta{}^{\text{``}}\tau_\eta .$$

$$[*100{\cdot}511] \qquad \supset . (\beta +_c 0)_\zeta = \tau_\zeta$$

Hence $\exists ! \beta$ is the requisite condition. Now since ζ can be in any type, we can also choose it in any existential type for τ. Thus with IIT applying to the arithmetical occurrence of τ in $f(\tau)$, we have, where τ is a formal number and β is a number in a definite type,

$$\vdash : \exists ! \beta . \beta = \tau . f(\tau) . \supset . f(\beta),$$

$$\vdash : \exists ! \beta . \beta = \tau . f(\beta) . \supset . f(\tau),$$

$$\vdash : \exists ! \sigma . \sigma = \tau . f(\tau) . \supset . f(\sigma).$$

In the last proposition by IT the equation $\sigma = \tau$ is arithmetical These equations are summed up in $*118{\cdot}01$.

These three fundamental theorems embody the principle of arithmetical substitution. The hypothesis $\exists ! \beta$ is really less than is assumed in ordinary life, the usual tacit assumption being $\beta \in \mathrm{NC} - \iota{}^{\backprime}\Lambda$. In fact unless $\beta \in \mathrm{NC}$, $\beta = \tau$ is necessarily false.

Principle of Identification of Types. Suppose we have proved "$\vdash : \mathrm{Hp} . \supset . \phi\sigma$" and "$\vdash : \phi(\sigma_\xi) . \supset . p$," where σ is a formal number whose occurrence in "$\vdash : \mathrm{Hp} . \supset . \phi\sigma$" is in an entirely ambiguous type, and σ_ξ is the same formal number σ with its type related to that of ξ by $*65{\cdot}01$. Then since the type of the σ in "$\vdash : \mathrm{Hp} . \supset . \phi\sigma$" is ambiguous, we can write "$\vdash : \mathrm{Hp} . \supset . \phi(\sigma_\xi)$," and thence infer "$\vdash . p$."

The principle is: An entirely undetermined type in an asserted symbolic form can be identified with any type ambiguous or otherwise in any other asserted symbolic form or in the same symbolic form.

For example in $*100{\cdot}42$ (demonstration) considered above, since $\exists ! \mu \cap \nu$ occurs, the first occurrences of $\mathrm{Nc}{}^{\backprime}\alpha$ and $\mathrm{Nc}{}^{\backprime}\beta$ are of the same type, and so are their second occurrences in $\mathrm{Nc}{}^{\backprime}\alpha = \mathrm{Nc}{}^{\backprime}\beta$. But the two types are not determined by our conventions to have any necessary connection. In fact the type in $\mathrm{Nc}{}^{\backprime}\alpha = \mathrm{Nc}{}^{\backprime}\beta$ is entirely arbitrary. Accordingly it can be identified with the other type, and thus the inference to the next line, *viz.* to "$\vdash : \mathrm{Hp} . \supset . \mu = \nu$," is justified.

In the case of arithmetical equations, it is important to notice that we have

$\vdash . *100{\cdot}321{\cdot}33 . \supset \vdash :. \exists ! \mathrm{Nc}(\xi)\text{‘}\alpha . \supset : \mathrm{Nc}(\xi)\text{‘}\alpha = \mathrm{Nc}(\xi)\text{‘}\beta . \supset . \mathrm{Nc}\text{‘}\alpha = \mathrm{Nc}\text{‘}\beta$.

Hence if σ and τ are formal numbers,

$$\vdash :. \exists ! \sigma_\xi . \supset : \sigma_\xi = \tau_\xi . \supset . \sigma = \tau.$$

Thus if we have "$\vdash : \mathrm{Hp} . \exists ! \sigma . \supset . \sigma = \tau$" and "$\vdash : \mathrm{Hp}' . \sigma_\eta = \tau_\eta . \supset . p$," we can infer from the former proposition "$\vdash : \mathrm{Hp} . \exists ! \sigma . \supset . \sigma_\eta = \tau_\eta$," and from this and the latter proposition, we infer "$\vdash : \mathrm{Hp}' . \mathrm{Hp} . \exists ! \sigma . \supset . p$," so the general principle of identification can be employed when the $\phi(\sigma)$ in the first proposition is an arithmetical equation.

For example, in an example given above, $*100{\cdot}44$ (demonstration), *viz.*

$$\vdash : \mu \in \mathrm{NC} . \exists ! \mathrm{Nc}\text{‘}\alpha . \alpha \in \mu . \supset . (\exists\beta) . \mu = \mathrm{Nc}\text{‘}\beta . \mathrm{Nc}\text{‘}\alpha = \mathrm{Nc}\text{‘}\beta,$$

the equation $\mathrm{Nc}\text{‘}\alpha = \mathrm{Nc}\text{‘}\beta$ is arithmetical. Accordingly we are justified in asserting the propositional function

$$\vdash : \mu \in \mathrm{NC} . \exists ! \mathrm{Nc}\text{‘}\alpha . \alpha \in \mu . \supset . (\exists\beta) . \mu = \mathrm{Nc}(\alpha)\text{‘}\beta . \mathrm{Nc}(\alpha)\text{‘}\alpha = \mathrm{Nc}(\alpha)\text{‘}\beta,$$

where $\mathrm{Nc}(\alpha)\text{‘}\beta$ in "$\mu = \mathrm{Nc}(\alpha)\text{‘}\beta$" has all along been presupposed by the necessity of meaning.

Thus the inference follows,

$$\vdash : \mu \in \mathrm{NC} . \exists ! \mathrm{Nc}\text{‘}\alpha . \alpha \in \mu . \supset . \mathrm{Nc}(\alpha)\text{‘}\alpha = \mu .$$
$$\supset . \mathrm{Nc}\text{‘}\alpha = \mu.$$

This proof loses its point when μ is looked on as a variable with necessarily the same type throughout. For then the proposition collapses into

$$\vdash :. \mu \in \mathrm{NC} . \supset : \alpha \in \mu . \equiv . \mathrm{Nc}(\alpha)\text{‘}\alpha = \mu.$$

But if μ be a formal number necessarily a member of NC, the proposition is really

$$\vdash :. \exists ! \mathrm{Nc}\text{‘}\alpha . \supset : \alpha \in \mu . \equiv . \mathrm{Nc}\text{‘}\alpha = \mu.$$

With this presupposition we should have in the first line of the demonstration

$$\text{“}\vdash : \exists ! \mathrm{Nc}\text{‘}\alpha . \mathrm{Nc}\text{‘}\alpha = \mu . \supset . \alpha \in \mu,\text{”}$$

though with "μ" a single variable, the line is formally correct as it stands in the text.

Recognition of Particular Cases. It is important to notice the conditions under which $\phi\sigma$ can be recognized as a particular case of $\phi\xi$, where ξ is a real variable and σ is a formal number. In the first place obviously we must substitute $\sigma \cap t_0\text{‘}\xi$ for σ, wherever it occurs in $\phi\sigma$, and thus obtain $\phi(\sigma \cap t_0\text{‘}\xi)$. Then we may find that by the application of our conventions, we can replace this by $\phi\sigma$. For example we have

$*100{\cdot}42$. $\vdash : \mu, \nu \in \mathrm{NC} . \exists ! \mu \cap \nu . \supset . \mu = \nu$

Now put $\text{Nc}'\alpha \cap t_0'\mu$ for μ, we obtain

$\vdash : \text{Nc}'\alpha \cap t_0'\mu, \nu \in \text{NC} . \exists ! (\text{Nc}'\alpha \cap t_0'\mu) \cap \nu . \supset . \text{Nc}'\alpha \cap t_0'\mu = \nu$ (1)

$\vdash . (1) . *100{\cdot}41 . \supset \vdash : \nu \in \text{NC} . \exists ! \text{Nc}'\alpha \cap t_0'\mu \cap \nu . \supset . \text{Nc}'\alpha \cap t_0'\mu = \nu$ (2)

Now by IT, even when ν is a formal number, the identity of types of the two occurrences of $\text{Nc}'\alpha$ is equally secured in

$$\vdash : \nu \in \text{NC} . \exists ! \text{Nc}'\alpha \cap \nu . \supset . \text{Nc}'\alpha = \nu.$$

Thus this is a particular case of $*100{\cdot}42$. Such deductions can be made in general without any explicit formal statement.

Ambiguity of NC. It follows (cf. $*100{\cdot}02$ and $*103{\cdot}02$) from the typical ambiguity of Nc that NC is also typically ambiguous. Hence "$\mu \in \text{NC} . \nu \in \text{NC}$" according to our methods of interpretation would not necessitate that μ and ν should be of the same type. We shall always interpret "$\mu, \nu \in \text{NC}$" as standing for "$\mu \in \text{NC} . \nu \in \text{NC}$" and therefore as not necessarily identifying the types of μ and ν. Similarly for N_0C, NC induct, and NC ind. For example

$*110{\cdot}402$. $\vdash : \mu, \nu \in \text{N}_0\text{C} . \supset . \exists ! (\mu +_c \nu) \cap t't'(\mu \uparrow \nu)$

Here the μ and ν need not be of the same type. Again

$*110{\cdot}41$. $\vdash : \mu, \nu \in \text{N}_0\text{C} . t'\mu = t'\nu . \supset . \exists ! (\mu +_c \nu) \cap t'\mu$

Here the identification of the types of μ and ν requires the hypothesis "$t'\mu = t'\nu$."

VI. *Conventions* AT *and* Infin T.

General Arithmetical Convention. Conventions IT and IIT are always applied, but the following convention is not used at first. This convention limits the remaining ambiguity of type by sweeping away the exceptional cases in low types, due to the failure of existence theorems. The convention will be cited as AT.

AT. *All equations involving pure arithmetical formal numbers are to be arithmetical.*

We have seen that from an arithmetical equation the analogous equation in any other type can be deduced. Thus with AT all equations between formal numbers are so determined in type that their truth in "any type" is deducible. Thus in the few early propositions where AT is introduced, the fact is noted by stating that the equations hold "in *any* type." These propositions are $*103{\cdot}16$, $*110{\cdot}71{\cdot}72$.

The effect of applying AT to other propositions in $*100$ is to render some of the hypotheses (usually logical forms affirming existence) unnecessary, but also materially to limit the scope of the propositions. Take for example

$*100{\cdot}35$. $\vdash : \exists ! \text{Nc}'\alpha . \vee . \exists ! \text{Nc}'\beta : \supset :$

$$\text{Nc}'\alpha = \text{Nc}'\beta . \equiv . \alpha \in \text{Nc}'\beta . \equiv . \beta \in \text{Nc}'\alpha . \equiv . \alpha \,\text{sm}\, \beta$$

If we apply AT to this, we can write

$$\vdash : \text{Nc}'\alpha = \text{Nc}'\beta . \equiv . \alpha \in \text{Nc}'\beta . \equiv . \beta \in \text{Nc}'\alpha . \equiv . \alpha \,\text{sm}\, \beta.$$

For the equational occurrences of $Nc'\alpha$ and $Nc'\beta$ are by A T and II T to be with adequate actual types. But if α is a small class in a high type, an adequate actual type for $Nc'\alpha$ will be a high type, whereas $\exists ! Nc'\alpha$ may hold in a low type. Thus with AT, for the sake of simplicity we abandon the statement of the minimum of hypothesis necessary for our propositions. The enunciation of no other proposition in $*100$ is affected.

The enunciation of no proposition in $*101$ is affected by A T, though it would unduly limit the scope of $*101\cdot34$. In $*110$, A T would unduly limit the scope of such propositions as

$$*110\cdot22\cdot23\cdot24\cdot25\cdot251\cdot252\cdot3\cdot31\cdot32\cdot331\cdot34\cdot35\cdot351\cdot44\cdot51\cdot54$$

and of many others, without altering their enunciations. There is no proposition in $*110$ whose enunciation it would alter. AT is already applied to $*110\cdot71\cdot72$; if AT is removed from these propositions, then $\exists ! Nc'\alpha$ must be added as an hypothesis to both of them. The effect of AT on $*113$ and $*116$ is entirely analogous to that on $*110$; in neither of these two numbers is there any proposition to which A T is applied in the text.

As regards $*117$, A T is applied throughout, so that the propositions are all in the form suitable for subsequent investigations in which the interest is purely arithmetical. It is important however to analyse the effect of AT on the enunciations for the sake of logical investigations, especially in connection with $*120$. First, AT can only affect propositions in which equations or inequations occur, and among such propositions it does not affect the enunciations of those in which both sides of the equations are not formal numbers, so that the equations are not arithmetical after the application of A T. These propositions are $*117\cdot104\cdot14\cdot24\cdot241\cdot243\cdot31\cdot551$. These propositions, which are characterized by the presence of a single letter on one side of any equation involved, can be recognized at a glance. The propositions involving arithmetical equations whose enunciations are unaltered by the removal of AT are $*117\cdot21\cdot54\cdot592$. Propositions involving inequations whose enunciations are unaltered by the removal of AT are $*117\cdot26\cdot27$. Finally the only propositions of $*117$ whose enunciations are altered by the removal of AT are $*117\cdot108\cdot211\cdot23\cdot25\cdot3$.

In $*118$ and $*119$ AT is not used.

In $*120$, which is devoted to those properties of inductive cardinals which are of logical interest, AT is never used. None of the propositions $*117\cdot108\cdot211\cdot23\cdot25\cdot3$ are cited in it, except $*117\cdot25$ in the demonstration of $*120\cdot435$ for a use where AT is not relevant. The application of AT to $*120$ would simplify the hypotheses of $*120\cdot31\cdot41\cdot451\cdot53\cdot55$, and limit the scopes of the propositions.

One other convention, which we will call "Infin T," is required in certain propositions where the hypothesis implies that there are types in which every

inductive cardinal exists, *i.e.* in which V is not an inductive class. Among such hypotheses are Infin ax, $\exists ! \text{Prog}$, $\exists ! \aleph_0$ (or typically definite forms of these hypotheses), or $R \in \text{Prog}$ or $\alpha \in \aleph_0$. When such hypotheses occur, we shall assume that NC induct is, whenever significance permits, to be determined in a type in which every inductive cardinal exists, *i.e.* in which the axiom of infinity holds (cf. $*120{\cdot}03{\cdot}04$). The statement of this convention is as follows:

Infin T. *When the hypothesis of a proposition implies that there is a type in which every inductive cardinal exists, every occurrence of* "NC induct" *in this proposition is to be taken (if conditions of significance permit) in a sufficiently high type to insure the existence of every inductive cardinal.*

It is to be observed that this convention would be unnecessary if we confined ourselves to one extensional hierarchy, for in any one such hierarchy all types are inductive or all are non-inductive, so that if every inductive cardinal exists in one type in the hierarchy, the same holds for any other type in the hierarchy. But when we no longer confine ourselves to one extensional hierarchy, this result may not follow. For example, it may be the case that the number of individuals is inductive, but the number of predicative functions of individuals is not inductive; at any rate, no *logical* reason can be given against this possibility, which can only be rejected on empirical grounds, if at all.

The way in which this convention is used may be illustrated by the demonstration of $*122{\cdot}33$. In the second line of this demonstration, we show that the hypothesis implies

$$\text{E}!\,\nu_R \,.\supset .\, \text{E}!\,(\nu +_c 1)_R \qquad (1)$$

where by $*121{\cdot}04$ $\qquad \nu_R = \breve{R}_{\nu -_c 1}{}^{\backprime}B{}^{\backprime}R \quad \text{Df},$

and by $*121{\cdot}02$ $\qquad R_\nu = \hat{x}\hat{y}\,\{\text{N}_0\text{c}{}^{\backprime}R\,(x \mapsto y) = \nu +_c 1\} \quad \text{Df}.$

It will be seen that these definitions do not suffice to determine the type of ν. Hence in (1), the ν on the left may not be of the same type as the $\nu +_c 1$ on the right. Now the use of $*120{\cdot}473$, which occurs in the next line of the demonstration of $*122{\cdot}33$, requires that the ν on the left and the $\nu +_c 1$ on the right should be of the same type. This requires that the ν should not be taken in a type in which we have $\exists !\,\nu \,.\, \nu +_c 1 = \Lambda$. Hence in order to apply $*120{\cdot}473$, we must choose a type in which all inductive cardinals exist. Since "$R \in \text{Prog}$" occurs in the hypothesis, we know that all inductive cardinals exist in the type of $C{}^{\backprime}R$. But it is unnecessary to restrict ourselves to the type of $C{}^{\backprime}R$, since any other type in which all inductive cardinals exist will equally secure the validity of the demonstration. Thus the convention Infin T secures the restriction required, and no more.

The convention Infin T is often relevant when "Infin ax" without any typical determination occurs in the hypothesis. Whenever this is the case,

if "NC induct" occurs in the proposition in a way which leaves its type undetermined so far as conditions of significance are concerned, it is to be taken in a type in which all its members exist.

VII. *Final Working Rule in Arithmetic.*

It is now (whenever AT is used, together with Infin T when necessary) possible finally to sweep aside all consideration of types in connection with inductive numbers. For by combining $*126\cdot121\cdot122$ and $*120\cdot4232\cdot4622$, we see that it is always possible to take the type high enough so that no definitely determined inductive number shall be null (Λ), and that all the inductive reasoning can take place within this type. Furthermore we have already seen that the arithmetical operations are independent of the types of the components, so long as they are existential. Thus, as far as the ordinary arithmetic of finite numbers is concerned, all the conventions (including AT), and the necessity for hypotheses as to the existence of inductive numbers, are finally superseded by the following single rule:

RULE OF INDEFINITE NUMBERS. *The type assigned to any symbol which represents an inductive number is such that the symbol is not equal to* Λ.

We make the definition

$*126\cdot01$. $\text{Nc ind} = \text{Nc induct} - \iota'\Lambda \quad \text{Df}$

Wherever this symbol "Nc ind" for the class of "indefinite inductive cardinal numbers" is used, the above rule is adhered to. In other words, "$\mu \epsilon \text{NC ind}$" can always be replaced by "$\mu = \text{Nc}'\alpha \,.\, \alpha \epsilon \text{Cls induct}$," where $\text{Nc}'\alpha$ is a homogeneous or ascending cardinal, and α is the appropriate constant, or is a variable, as the case may be. In the latter case, a symbolic form such as

$$(\mu) \,.\, f(\mu \epsilon \text{NC ind}, \mu)$$

can be replaced by

$$(\mu, \alpha) \,.\, f(\mu = \text{Nc}'\alpha \,.\, \alpha \epsilon \text{Cls induct}, \mu).$$

Furthermore by $*120\cdot4622$ it follows that with this rule the result of proceeding by induction in one type and then transforming to another type is the same as that of proceeding by induction in the latter type. Thus for example there is no advantage to be gained by discriminating between 2_ξ and 2_η; for $\text{sm}_\eta{}''2_\xi = 2_\eta$, $\text{sm}_\xi{}''2_\eta = 2_\xi$, $\mu +_c 2_\xi = \mu +_c 2_\eta$, $\mu \times_c 2_\xi = \mu \times_c 2_\eta$, $\mu^2{}_\xi = \mu^2{}_\eta$, $2_\xi{}^\mu = 2_\eta{}^\mu$, and $\mu \geqslant 2_\xi \,.\, \equiv \,.\, \mu \geqslant 2_\eta$, and so on.

Hence all discrimination of the types of indefinite inductive numbers may be dropped; and the types are entirely indefinite and irrelevant.

PART III

CARDINAL ARITHMETIC

SUMMARY OF PART III

IN this Part, we shall be concerned, first, with the definition and general logical properties of cardinal numbers (Section A); then with the operations of addition, multiplication and exponentiation, of which the definitions and formal laws do not require any restriction to finite numbers (Section B); then with the theory of finite and infinite, which is rendered somewhat complicated by the fact that there are two different senses of "finite," which cannot (so far as is known) be identified without assuming the multiplicative axiom. The theory of finite and infinite will be resumed, in connection with series, in Part V, Section E.

It is in this Part that the theory of types first becomes practically relevant. It will be found that contradictions concerning the maximum cardinal are solved by this theory. We have therefore devoted our first section in this Part (with the exception of two numbers giving the most elementary properties of cardinals in general, and of 0 and 1 and 2, respectively) to the application of types to cardinals. Every cardinal is typically ambiguous, and we confer typical definiteness by the notations of $*63$, $*64$, and $*65$. It is especially where existence-theorems are concerned that the theory of types is essential. The chief importance of the propositions of the present part lies, not only, as throughout the book, in the hypotheses necessary to secure the conclusions, but also in the typical ambiguity which can be allowed to the symbols consistently with the truth of the propositions in all the cases thereby included.

SECTION A

DEFINITION AND LOGICAL PROPERTIES OF CARDINAL NUMBERS

Summary of Section A.

The Cardinal Number of a class α, which we will denote by "$\text{Nc}{}^{\backprime}\alpha$," is defined as the class of all classes similar to α, *i.e.* as $\hat{\beta}(\beta \text{ sm } \alpha)$. This definition is due to Frege, and was first published in his *Grundlagen der Arithmetik**; its symbolic expression and use are to be found in his *Grundgesetze der Arithmetik*†. The chief merits of this definition are (1) that the formal properties which we expect cardinal numbers to have result from it; (2) that unless we adopt this definition or some more complicated and practically equivalent definition, it is necessary to regard the cardinal number of a class as an indefinable. Hence the above definition avoids a useless indefinable with its attendant primitive propositions.

It will be observed that, if x is any object, 1 is not the cardinal number of x, but that of $\iota{}^{\backprime}x$. This obviates a confusion which otherwise is liable to arise in dealing with classes. Suppose we have a class α consisting of many terms; we say, nevertheless, that it is *one* class. Thus it seems to be at once one and many. But in fact it is α that is many, and $\iota{}^{\backprime}\alpha$ that is one. In regard to zero, the analogous point is still clearer. Suppose we say "there are no Kings of France." This is equivalent to "the class of Kings of France has no members," or, in our language, "the class of Kings of France is a member of the class 0." It is obvious that we cannot say "the King of France is a member of the class 0," because there is no King of France. Thus in the case of 0 and 1, as more evidently in all other cases, a cardinal number appertains to a class, not to the members of the class.

For the purposes of formal definition, we subject the formula

$$\text{Nc}{}^{\backprime}\alpha = \hat{\beta}(\beta \text{ sm } \alpha)$$

to some simplification. It will be seen that, according to this formula, "Nc" is a relation, namely the relation of a cardinal number to any class of which it is the number. Thus for example 1 has to $\iota{}^{\backprime}x$ the relation Nc; so has 2 to $\iota{}^{\backprime}x \cup \iota{}^{\backprime}y$, provided $x \neq y$. The relation Nc is, in fact, the relation $\overrightarrow{\text{sm}}$; for $\overrightarrow{\text{sm}}{}^{\backprime}\alpha = \hat{\beta}(\beta \text{ sm } \alpha)$. Hence for formal purposes of definition we put

$$\text{Nc} = \overrightarrow{\text{sm}} \quad \text{Df.}$$

* Breslau, 1884. Cf. especially pp. 79, 80.

† Jena, Vol. I. 1893, Vol. II. 1903. Cf. Vol. I. §§ 40—42, pp. 57, 58. The grounds in favour of this definition will be found at length in *Principles of Mathematics*, Part II.

The class of cardinal numbers is the class of objects which are the cardinal numbers of something or other, *i.e.* of objects which, for some α, are equal to $\text{Nc}'\alpha$. We call the class of cardinal numbers NC; thus we have

$$\text{NC} = \hat{\mu}\{(\exists\alpha) \,.\, \mu = \text{Nc}'\alpha\}.$$

For purposes of formal definition, we replace this by the simpler formula

$$\text{NC} = \text{D}'\text{Nc} \quad \text{Df.}$$

In the present section, we shall be concerned with what we may call the purely logical properties of cardinal numbers, namely those which do not depend upon the arithmetical operations of addition, multiplication and exponentiation, nor upon the distinction of finite and infinite*. The chief point to be dealt with, as regards both importance and difficulty, is the relation of a cardinal number in one type to the same or an associated cardinal number in another type. When a symbol is ambiguous as to type, we will call it *typically ambiguous*; when, either always or in a given context, it is unambiguous as to type, we will call it *typically definite*. Now the symbol "sm" is typically ambiguous; the only limitation on its type is that its domain and converse domain must both consist of classes. When we have $\alpha \,\text{sm}\, \beta$, α and β need not be of the same type, in fact, in any type of classes, there are classes similar to some of the classes of any other type of classes. For example, we have $\iota'x \,\text{sm}\, \iota'y$, whatever types x and y may belong to. This ambiguity of "sm" is derived from that of $1 \rightarrow 1$, which in turn is derived from that of 1. We denote (cf. $*65{\cdot}01$) by "1_α" all the unit classes which are of the same type as α. Then (according to the definition $*70{\cdot}01$) $1_\alpha \rightarrow 1_\beta$ will be the class of those one-one relations whose domain is of the same type as α and whose converse domain is of the same type as β. Thus "$1_\alpha \rightarrow 1_\beta$" is typically definite as soon as α and β are given. Suppose now, instead of having merely $\gamma \,\text{sm}\, \delta$, we have

$$(\exists R) \,.\, R \in 1_\alpha \rightarrow 1_\beta \,.\, \text{D}'R = \gamma \,.\, \text{Ꮧ}'R = \delta;$$

then we know not only that $\gamma \,\text{sm}\, \delta$, but also that γ belongs to the same type as α, and δ belongs to the same type as β. When the ambiguous symbol "sm" is rendered typically definite by having its domain defined as being of the same type as α, and its converse domain defined as being of the same type as β, we write it "$\text{sm}_{(\alpha,\beta)}$," because generally, in accordance with $*65{\cdot}1$, if R is a typically ambiguous relation, we write $R_{(\alpha,\beta)}$ for the typically definite relation that results when the domain of R is to consist of terms of the same type as α, and the converse domain is to consist of terms of the same type as β. Thus we have

$$\gamma \,\text{sm}_{(\alpha,\beta)}\, \delta \,.\equiv.\, (\exists R) \,.\, R \in 1_\alpha \rightarrow 1_\beta \,.\, \gamma = \text{D}'R \,.\, \delta = \text{Ꮧ}'R.$$

Here everything is typically definite if α and β (or their types) are given.

* The definitions of the arithmetical operations, and of finite and infinite, are really just as purely logical as what precedes them; but if we are to draw a line between logic and arithmetic somewhere, the arithmetical operations seem the natural point at which to place the beginning of arithmetic.

Passing now to the relation "Nc," it will be seen that it shares the typical ambiguity of "sm." In order to render it typically definite, we must derive it from a typically definite "sm." So long as nothing is added to give typical definiteness, "Nc‘γ" will mean all the classes belonging to some one (unspecified) type and similar to γ. If α is a member of the type to which these classes are to belong, then Nc‘γ is contained in the type of α. For this case, it is convenient to introduce the following two notations, already defined in ∗65. When a typically ambiguous relation R is to be rendered typically definite as to its domain only, by deciding that every member of the domain is to be *contained in* the type of α, we write "$R(\alpha)$" in place of R. When we further wish to determine R as having members of the converse domain *contained in* the type of β, we write "$R(\alpha, \beta)$" in place of R; and when we wish members of the converse domain to be *members of* the type of β, we write "$R(\alpha_\beta)$" in place of R. Thus

$$\text{sg}`\{R_{(\alpha,\beta)}\} = \{\text{sg}`R\}(\alpha_\beta)$$

(cf. ∗65·2), and in particular, since $\text{Nc} = \overrightarrow{\text{sm}}$,

$$\text{Nc}(\alpha_\beta) = \text{sg}`\text{sm}_{(\alpha,\beta)}.$$

Thus "$\text{Nc}(\alpha_\beta)`\gamma$" is only significant when γ is of the same type as β, and then it means "classes of the same type as α and similar to γ (which is of the same type as β)."

"$\text{Nc}(\alpha)`\gamma$" will mean "classes of the same type as $\alpha$ and similar to $\gamma$." As soon as the types of $\alpha$ and $\gamma$ are known, this is a typically definite symbol, being in fact equal to $\text{Nc}(\alpha_\gamma)`\gamma$. Hence so long as we only wish to consider "Nc‘γ," typical definiteness is secured by writing "$\text{Nc}(\alpha)$" in place of "Nc."

When we come to the consideration of NC, "$\text{Nc}(\alpha)$" is no longer a sufficient determination, although it suffices to determine the type. Suppose we put

$$\text{NC}^\beta(\alpha) = \text{D}`\text{Nc}(\alpha_\beta) \quad \text{Df};$$

we have also, in virtue of the definitions in ∗65,

$$\text{NC}(\alpha) = \text{NC} \cap t^{2}`\alpha = \text{D}`\text{Nc}(\alpha).$$

Thus $\text{NC}(\alpha)$ is definite as to type, but is the domain of a relation whose converse domain is ambiguous as to type; and it will appear that there are some propositions about $\text{NC}(\alpha)$ whose truth or falsehood depends upon the determination chosen for the converse domain of $\text{Nc}(\alpha)$. Hence if we wish to have a symbol which is completely definite, we must write "$\text{NC}^\beta(\alpha)$."

This point is important in connection with the contradictions as to the maximum cardinal. The following remarks will illustrate it further.

Cantor has shown that, if β is any class, no class contained in β is similar to Cl‘β. Hence in particular if β is a type, no class contained in β is similar

to $\text{Cl}'\beta$, which is the next type above β. Consequently, if $\beta = \alpha \cup -\alpha$, where α is any class, we have

$$\sim(\exists\gamma) \, . \, \gamma \subset \alpha \cup -\alpha \, . \, \gamma \operatorname{sm} \text{Cl}'(\alpha \cup -\alpha).$$

Now (cf. $*63$) we put

$$t_0{}'\alpha = \alpha \cup -\alpha \quad \text{Df},$$

and we have $t'\alpha = \text{Cl}'(\alpha \cup -\alpha)$. Thus we find

$$\sim(\exists\gamma) \, . \, \gamma \subset t_0{}'\alpha \, . \, \gamma \operatorname{sm} t'\alpha.$$

Hence $$\text{Nc}\,(\alpha_{t'\alpha})'t'\alpha = \Lambda.$$

That is to say, no class of the same type as α has as many members as $t'\alpha$ has. Hence also

$$\Lambda \in \text{NC}^{t'\alpha}\,(\alpha).$$

But $$\gamma \subset t_0{}'\alpha \, . \supset . \, \gamma \in \text{Nc}\,(\alpha_\alpha)'\gamma \, . \supset . \, \exists \,!\, \text{Nc}\,(\alpha_\alpha)'\gamma,$$

and "$\text{Nc}\,(\alpha_\alpha)'\gamma$" is only significant when $\gamma \subset t_0{}'\alpha$; hence

$$\mu \in \text{NC}^\alpha\,(\alpha) \, . \supset_\mu . \, \exists \,!\, \mu$$

and $$\Lambda \sim\in \text{NC}^\alpha\,(\alpha).$$

Now the notation "$\text{NC}\,(\alpha)$" will apply with equal justice to $\text{NC}^\alpha\,(\alpha)$ or to $\text{NC}^{t'\alpha}\,(\alpha)$; but we have just seen that in the first case we shall have $\Lambda \sim\in \text{NC}\,(\alpha)$, and in the second we shall have $\Lambda \in \text{NC}\,(\alpha)$. Consequently "$\text{NC}\,(\alpha)$" has not sufficient definiteness to prevent practically important differences between the various determinations of which it is capable.

A converse procedure to the above yields similar results. Let α be a class of classes; then $s'\alpha$ is of lower type than α. Let us consider $\text{NC}^{s'\alpha}\,(\alpha)$. In accordance with $*63$, we write $t_1{}'\alpha$ for the type containing $s'\alpha$, *i.e.* for $s'\alpha \cup -s'\alpha$. Then the greatest number in the class $\text{NC}^{s'\alpha}\,(\alpha)$ will be $\text{Nc}\,(\alpha)'t_1{}'\alpha$; but neither this nor any lesser member of the class will be equal to $\text{Nc}\,(\alpha)'t_0{}'\alpha$, because, as before,

$$\sim(\exists\gamma) \, . \, \gamma \subset t_1{}'\alpha \, . \, \gamma \operatorname{sm} t_0{}'\alpha.$$

Hence $\text{Nc}\,(\alpha)'t_0{}'\alpha$, which is a member of $\text{NC}^\alpha\,(\alpha)$, is not a member of $\text{NC}^{s'\alpha}\,(\alpha)$; but $\text{NC}^\alpha\,(\alpha)$ and $\text{NC}^{s'\alpha}\,(\alpha)$ have an equal right to be called $\text{NC}\,(\alpha)$. Hence again "$\text{NC}\,(\alpha)$" is a symbol not sufficiently definite for many of our purposes.

The solution of the paradox concerning the maximum cardinal is evident in view of what has been said. This paradox is as follows: It results from a theorem of Cantor's that there is no maximum cardinal, since, for all values of α,

$$\text{Nc}'\text{Cl}'\alpha > \text{Nc}'\alpha.$$

But at first sight it would seem that the class which contains everything must be the greatest possible class, and must therefore contain the greatest possible number of terms. We have seen, however, that a class α must always be contained within some one type; hence all that is proved is that there are greater classes in the next type, which is that of $\text{Cl}'\alpha$. Since there is always a next higher type, we thus have a maximum cardinal in each type, without

having any absolutely maximum cardinal. The maximum cardinal in the type of α is

$$\mathrm{Nc}\,(\alpha)\text{‘}(\alpha \cup -\alpha).$$

But if we take the corresponding cardinal in the next type, *i.e.*

$$\mathrm{Nc}\,(\mathrm{Cl}\text{‘}\alpha)\text{‘}(\alpha \cup -\alpha),$$

this is not as great as $\mathrm{Nc}\,(\mathrm{Cl}\text{‘}\alpha)\text{‘}\mathrm{Cl}\text{‘}(\alpha \cup -\alpha)$, and is therefore not the maximum cardinal of its type. This gives the complete solution of the paradox.

For most purposes, what we wish to know in order to have a sufficient amount of typical definiteness is not the absolute types of α and β, as above, but merely what we may call their *relative* types. Thus, for example, α and β may be of the same type; in that case, $\mathrm{Nc}\,(\alpha_\beta)$ and $\mathrm{NC}^\beta\,(\alpha)$ are respectively equal to $\mathrm{Nc}\,(\alpha_\alpha)$ and $\mathrm{NC}^\alpha\,(\alpha)$. We will call cardinals which, for some α, are members of the class $\mathrm{NC}^\alpha\,(\alpha)$, *homogeneous* cardinals, because the "sm" from which they are derived is a homogeneous relation. We shall denote the homogeneous cardinal of α by "$\mathrm{N_0c}\text{‘}\alpha$," and we shall denote the class of homogeneous cardinals (in an unspecified type) by "$\mathrm{N_0C}$"; thus we put

$$\mathrm{N_0c}\text{‘}\alpha = \mathrm{Nc}\text{‘}\alpha \cap t\text{‘}\alpha \quad \mathrm{Df},$$

$$\mathrm{N_0C} = \mathrm{D}\text{‘}\mathrm{N_0c} \qquad \mathrm{Df}.$$

Almost all the properties of $\mathrm{N_0C}$ are the same in different types. When further typical definiteness is required, it can be secured by writing $\mathrm{N_0c}\,(\alpha)$, $\mathrm{N_0C}\,(\alpha)$ in place of $\mathrm{N_0c}$, $\mathrm{N_0C}$. For although $\mathrm{Nc}\,(\alpha)$ and $\mathrm{NC}\,(\alpha)$ were not wholly definite, $\mathrm{N_0c}\,(\alpha)$ and $\mathrm{N_0C}\,(\alpha)$ are wholly definite. Apart from the fact of being of different types, the only property in which $\mathrm{N_0C}\,(\alpha)$ and $\mathrm{N_0C}\,(\beta)$ differ when α and β are of different types is in regard to the magnitude of the cardinals belonging to them. Thus suppose the whole universe consisted (as monists aver) of a single individual. Let us call the type of this individual "Indiv." Then $\mathrm{N_0C}\,(\mathrm{Indiv})$ will consist of 0 and 1, *i.e.*

$$\mathrm{N_0C}\,(\mathrm{Indiv}) = \iota\text{‘}0 \cup \iota\text{‘}1.$$

But in the next higher type, there will be two members, namely Λ and Indiv. Thus

$$\mathrm{N_0C}\,(t\text{‘}\mathrm{Indiv}) = \iota\text{‘}0 \cup \iota\text{‘}1 \cup \iota\text{‘}2.$$

Similarly $\quad \mathrm{N_0C}\,(t\text{‘}t\text{‘}\mathrm{Indiv}) = \iota\text{‘}0 \cup \iota\text{‘}1 \cup \iota\text{‘}2 \cup \iota\text{‘}3 \cup \iota\text{‘}4,$

the members of $t\text{‘}t\text{‘}\mathrm{Indiv}$ being $\Lambda \cap t\text{‘}\mathrm{Indiv}$, $\iota\text{‘}\Lambda$, $\iota\text{‘}\mathrm{Indiv}$, $\iota\text{‘}\Lambda \cup \iota\text{‘}\mathrm{Indiv}$; and so on. (The greatest cardinal in any except the lowest type is always a power of 2.)

The maximum of $\mathrm{N_0C}\,(\alpha)$ is $\mathrm{N_0c}\text{‘}t_0\text{‘}\alpha$; but apart from this difference of maximum and its consequences, $\mathrm{N_0C}\,(\alpha)$ and $\mathrm{N_0C}\,(\beta)$ do not differ in any important properties. Hence for most purposes $\mathrm{N_0C}$ and $\mathrm{N_0c}$ have as much typical definiteness as is necessary.

Among cardinals which are not homogeneous we shall consider three kinds. The first of these we shall call *ascending* cardinals. A cardinal $\mathrm{NC}^\beta\,(\alpha)$ is

called an *ascending* cardinal if the type of β is t'α or t't'α or t't't'α or etc. We write t^2'α for t't'α, t^3'α for t't't'α, and so on. We put

$$N^1c`\alpha = Nc`\alpha \cap t`t`\alpha \quad Df$$

$$N^2c`\alpha = Nc`\alpha \cap t`t^2`\alpha \quad Df$$

$$N^3c`\alpha = Nc`\alpha \cap t`t^3`\alpha \quad Df \quad \text{and so on,}$$

and

$$N^1C = D`N^1c \quad Df$$

$$N^2C = D`N^2c \quad Df$$

$$N^3C = D`N^3c \quad Df \quad \text{and so on.}$$

We then have obviously

$$N^1C\,(t`\alpha) \subset N_0C\,(t`\alpha).$$

We also have (by what was said earlier)

$$N_0c`t`\alpha \sim\epsilon\, N^1C\,(t`\alpha).$$

Hence

$$\exists !\, N_0C\,(t`\alpha) - N^1C\,(t`\alpha).$$

The members of $N_0C\,(t`\alpha) - N^1C\,(t`\alpha)$ will be all cardinals which exceed $Nc`t_0`\alpha$ but do not exceed $Nc`t`\alpha$.

Let us recur in illustration to our previous hypothesis of the universe consisting of a single individual. Then $N^1c`\text{Indiv}$ will consist of those classes which are similar to "Indiv" but of the next higher type. These are $\iota`\Lambda$ and $\iota`\text{Indiv}$. In our case we had $N_0c`\text{Indiv} = 1$. This leads to

$$N^1c`\text{Indiv} = 1 \,.\, N^2c`\text{Indiv} = 1 \text{ etc.}$$

or, introducing typical definiteness,

$$N^1c`\text{Indiv} = 1\,(t`\text{Indiv}) \,.\, N^2c`\text{Indiv} = 1\,(t^2`\text{Indiv}) \text{ etc.}$$

We have then $1\,(t`\text{Indiv}) \,\epsilon\, N^1C\,(t`t`\text{Indiv})$. Also

$$1\,(t`\text{Indiv}) \,\epsilon\, N_0C\,(t`t`\text{Indiv}).$$

And in the case supposed, $1\,(t`\text{Indiv})$ is the maximum of $N^1C\,(t`t`\text{Indiv})$, but $2\,(t`\text{Indiv}) \,\epsilon\, N_0C\,(t`t`\text{Indiv})$. Hence

$$N_0C\,(t`t`\text{Indiv}) - N^1C\,(t`t`\text{Indiv}) = \iota`2.$$

Generalizing, we see that $N^1C\,(t`\alpha)$ consists of the same numbers as $N_0C\,(\alpha)$ each raised one degree in type. Similar propositions hold of $N^2C\,(t^2`\alpha)$, $N^3C\,(t^3`\alpha)$ etc.

It is often useful to have a notation for what we may call "the same cardinal in another type." Suppose μ is a typically definite cardinal; then we will denote by $\mu^{(1)}$ the same cardinal in the next type, *i.e.*

$$sm``\mu \cap t`\mu.$$

Note that, if μ is a cardinal, $sm``\mu \cap \mu = \mu$; and whether μ is a typically definite cardinal or not,

$$sm``\mu \cap t`\alpha$$

is a cardinal in a definite type. If μ is typically definite, then $sm``\mu \cap t`\alpha$ is wholly definite; if $\mu$ is typically ambiguous, $sm``\mu \cap t`\alpha$ has the same kind of

indefiniteness as belongs to $\mathrm{NC}(\alpha)$. The most important case is when μ is typically definite and α has an assigned relation of type to μ. We then put, as observed above,

$$\mu^{(1)} = \mathrm{sm}``\mu \cap t`\mu \quad \mathrm{Df}$$

$$\mu^{(2)} = \mathrm{sm}``\mu \cap t^2`\mu \quad \mathrm{Df\ etc.}$$

If μ is an $\mathrm{N_0C}$, $\mu^{(1)}$ is an $\mathrm{N^1C}$ and $\mu^{(2)}$ is an $\mathrm{N^2C}$ and so on. $\mathrm{N^1C}(t`\alpha)$ will consist of all numbers which are of the form $\mu^{(1)}$ for some μ which is a member of $\mathrm{N_0C}(\alpha)$; *i.e.*

$$\mathrm{N^1C}(t`\alpha) = \hat{\nu}\{(\exists\mu) \,.\, \mu \in \mathrm{N_0C}(\alpha) \,.\, \nu = \mu^{(1)}\}.$$

The second kind of non-homogeneous cardinals to be considered is called the class of "descending cardinals." These are such as go into a lower type; *i.e.* $\mathrm{Nc}(\alpha)`\beta$ is a descending cardinal if α is of a lower type than β. We put

$$\mathrm{N_1c}`\alpha = \mathrm{Nc}`\alpha \cap t`t_1`\alpha \quad \mathrm{Df}$$

$$\mathrm{N_2c}`\alpha = \mathrm{Nc}`\alpha \cap t`t_2`\alpha \quad \mathrm{Df\ etc.}$$

$$\mathrm{N_1C} = \mathrm{D}`\mathrm{N_1c} \quad \mathrm{Df}$$

$$\mathrm{N_2C} = \mathrm{D}`\mathrm{N_2c} \quad \mathrm{Df\ etc.}$$

$$\mu_{(1)} = \mathrm{sm}``\mu \cap t_1`\mu \quad \mathrm{Df}$$

$$\mu_{(2)} = \mathrm{sm}``\mu \cap t_2`\mu \quad \mathrm{Df\ etc.}$$

We have obviously $\qquad \mathrm{N_0c}`\alpha = \mathrm{N_1c}`\iota``\alpha.$

Hence $\qquad \mathrm{N_0C}(\alpha) \subset \mathrm{N_1C}(\alpha).$

Also $\qquad \gamma \in \mathrm{N_1c}`\delta \,.\supset .\, \mathrm{N_1c}`\delta = \mathrm{N_0c}`\gamma,$

whence $\qquad \exists\,!\,\mathrm{N_1c}`\delta \,.\supset .\, \mathrm{N_1c}`\delta \in \mathrm{N_0C},$

whence $\qquad \mathrm{N_1C} - \iota`\Lambda \subset \mathrm{N_0C}.$

Since also $\Lambda \sim\in \mathrm{N_0C}(\alpha)$, we find

$$\mathrm{N_0C} = \mathrm{N_1C} - \iota`\Lambda,$$

this proposition not requiring any further typical definiteness, since it holds however such definiteness may be introduced, remembering that such definiteness is necessarily so introduced as to secure significance. Further, in virtue of the fact that no class contained in $t_0`\alpha$ is similar to $t`\alpha$, we have

$$\Lambda \in \mathrm{N_1C}(\alpha).$$

Consequently $\qquad \mathrm{N_1C} = \mathrm{N_0C} \cup \iota`\Lambda.$

We can prove in just the same way

$$\mathrm{N_2C} = \mathrm{N_0C} \cup \iota`\Lambda.$$

Hence $\qquad \mathrm{N_1C} = \mathrm{N_2C},$

and this result can obviously be extended to all descending cardinals.

The third kind of non-homogeneous cardinals to be considered may be called "relational cardinals." They are those applicable to classes of relations having a given relation of type to a given class. Consider for example $\mathrm{Nc}`\epsilon_\Delta`\kappa$. (We shall take this as the definition of the product of the numbers of the

members of κ.) Suppose now that κ consists of a single term: we want to be able to say

$$\mathrm{Nc}\text{‘}\epsilon_\Delta\text{‘}\kappa = \mathrm{Nc}\text{‘}\breve{\iota}\text{‘}\kappa.$$

We have in this case, if $\kappa = \iota\text{‘}\alpha$,

$$\epsilon_\Delta\text{‘}\kappa = \downarrow \alpha\text{‘‘}\alpha,$$

and we know that $\downarrow \alpha\text{‘‘}\alpha \,\mathrm{sm}\, \alpha$. But if we put simply

$$\mathrm{Nc}\text{‘} \downarrow \alpha\text{‘‘}\alpha = \mathrm{Nc}\text{‘}\alpha,$$

our proposition, though not mistaken, requires care in interpretation. Just as we put $\iota\text{‘‘}\alpha \in \mathrm{N}^1\mathrm{c}\text{‘}\alpha$, so we want a notation giving typical definiteness to the proposition $\downarrow \alpha\text{‘‘}\alpha \in \mathrm{Nc}\text{‘}\alpha$. This is provided as follows.

Using the notation of $*64$, put

$$\mathrm{N}_{00}\mathrm{c}\text{‘}\alpha = \mathrm{Nc}\text{‘}\alpha \cap t\text{‘}t_{00}\text{‘}\alpha \quad \mathrm{Df}$$
$$\mathrm{N}_0{}^1\mathrm{c}\text{‘}\alpha = \mathrm{Nc}\text{‘}\alpha \cap t\text{‘}t_0{}^1\text{‘}\alpha \quad \mathrm{Df\ etc.}$$
$$\mathrm{N}_{00}\mathrm{C} = \mathrm{D}\text{‘}\mathrm{N}_{00}\mathrm{c} \quad \mathrm{Df}$$
$$\mathrm{N}_0{}^1\mathrm{C} = \mathrm{D}\text{‘}\mathrm{N}_0{}^1\mathrm{c} \quad \mathrm{Df\ etc.}$$
$$\mu_{(00)} = \mathrm{sm}\text{‘‘}\mu \cap t\text{‘}t_{00}\text{‘}t_1\text{‘}\mu \quad \mathrm{Df\ etc.}$$

Then we have, for example,

$$\downarrow \alpha\text{‘‘}\alpha \subset t_0{}^1\text{‘}\alpha, \quad i.e. \downarrow \alpha\text{‘‘}\alpha \in t\text{‘}t_0{}^1\text{‘}\alpha.$$

Hence $\downarrow \alpha\text{‘‘}\alpha \in \mathrm{N}_0{}^1\mathrm{c}\text{‘}\alpha$, where $\mathrm{N}_0{}^1\mathrm{c}\text{‘}\alpha = \mathrm{Nc}\text{‘}\alpha \cap t\text{‘}t_0{}^1\text{‘}\alpha$.

Similarly $\quad x \in t\text{‘}\alpha \,.\supset.\, \downarrow x\text{‘‘}\alpha \in \mathrm{N}_{00}\mathrm{c}\text{‘}\alpha.$

Thus the above definitions give us what is required.

In order to complete our notation for types, we should need to be able to express the type of the domain or converse domain of R, or of any relation whose domain and converse domain have respectively given relations of type to the domain and converse domain of R. Thus we might put

$$\mathrm{d}_0\text{‘}R = t_0\text{‘}\mathrm{D}\text{‘}R \quad \mathrm{Df}$$
$$\mathrm{b}_0\text{‘}R = t_0\text{‘}\mathrm{G}\text{‘}R \quad \mathrm{Df}$$

("b" appears here as "d" written backwards)

$$\mathrm{d}_{00}\text{‘}R = t\text{‘}(\mathrm{d}_0\text{‘}R \uparrow \mathrm{b}_0\text{‘}R) \quad \mathrm{Df}$$
$$= t\text{‘}R$$
$$\mathrm{d}^{mn}\text{‘}R = t\text{‘}(t^m\text{‘}\mathrm{d}_0\text{‘}R \uparrow t^n\text{‘}\mathrm{b}_0\text{‘}R) \quad \mathrm{Df\ and\ so\ on.}$$

This notation would enable us to deal with descending relational cardinals. But it is not required in the present work, and is therefore not introduced among the numbered propositions.

When a typically ambiguous symbol, such as "sm" or "Nc," occurs more than once in a given context, it must not be assumed, unless required by the conditions of significance, that it is to receive the same typical determination in each case. Thus *e.g.* we shall write "$\alpha \,\mathrm{sm}\, \beta \,.\supset.\, \beta \,\mathrm{sm}\, \alpha$," although, if α and β are of different types, the two symbols "sm" must receive different typical determinations.

Formulae which are typically ambiguous, or only partially definite as to type, must not be admitted unless every significant interpretation is true. Thus for example we may admit

$$\text{“} \vdash . \alpha \in \text{Nc}`\alpha \text{”}$$

because here "Nc" must mean "$\text{Nc}(\alpha_\alpha)$," so that the only ambiguity remaining is as to the type of α, and the formula holds whatever type α may belong to, provided "$\text{Nc}`\alpha$" is significant, *i.e.* provided $\alpha$ is a class. But we must not, from "$\alpha \in \text{Nc}`\alpha$," allow ourselves to infer

$$\text{“} \exists ! \text{Nc}`\alpha \text{.”}$$

For here the conditions of significance no longer demand that "Nc" should mean "$\text{Nc}(\alpha_\alpha)$": it might just as well mean "$\text{Nc}(\beta_\alpha)$." And as we saw, if β is a lower type than α, and α is sufficiently large of its type, we may have

$$\text{Nc}(\beta_\alpha)`\alpha = \Lambda,$$

so that "$\exists ! \text{Nc}`\alpha$" is not admissible without qualification. Nevertheless, as we shall see in $*100$, there are a certain number of propositions to be made about a wholly ambiguous Nc or NC.

$*100$. DEFINITION AND ELEMENTARY PROPERTIES OF CARDINAL NUMBERS

Summary of $*100$.

In this number we shall be concerned only with such immediate consequences of the definition of cardinal numbers as do not require typical definiteness, beyond what the inherent conditions of significance may bestow. We introduce here the fundamental definitions:

$*100{\cdot}01$. $\text{Nc} = \overrightarrow{\text{sm}}$ Df

$*100{\cdot}02$. $\text{NC} = \text{D}‘\text{Nc}$ Df

The definition "Nc" is required chiefly for the sake of the descriptive function $\text{Nc}‘\alpha$. We have

$*100{\cdot}1$. $\vdash . \text{Nc}‘\alpha = \hat{\beta}(\beta \mathrel{\breve{\text{sm}}} \alpha) = \hat{\beta}(\alpha \mathrel{\text{sm}} \beta)$

This may be stated in various equivalent forms, which are given at the beginning of this number ($*100{\cdot}1$—$\cdot16$). After a few propositions on Nc as a relation, we proceed to the elementary properties of $\text{Nc}‘\alpha$. We have

$*100{\cdot}3$. $\vdash . \alpha \in \text{Nc}‘\alpha$

$*100{\cdot}31$. $\vdash : \alpha \in \text{Nc}‘\beta . \equiv . \beta \in \text{Nc}‘\alpha . \equiv . \alpha \mathrel{\text{sm}} \beta$

$*100{\cdot}321$. $\vdash : \alpha \mathrel{\text{sm}} \beta . \supset . \text{Nc}‘\alpha = \text{Nc}‘\beta$

$*100{\cdot}33$. $\vdash : \exists ! \text{Nc}‘\alpha \cap \text{Nc}‘\beta . \supset . \alpha \mathrel{\text{sm}} \beta$

We proceed next to the elementary properties of NC. We have

$*100{\cdot}4$. $\vdash : \mu \in \text{NC} . \equiv . (\exists \alpha) . \mu = \text{Nc}‘\alpha$

$*100{\cdot}42$. $\vdash : \mu, \nu \in \text{NC} . \exists ! \mu \cap \nu . \supset . \mu = \nu$

$*100{\cdot}45$. $\vdash : \mu \in \text{NC} . \alpha \in \mu . \supset . \text{Nc}‘\alpha = \mu$

$*100{\cdot}51$. $\vdash : \mu \in \text{NC} . \alpha \in \mu . \supset . \text{sm}“\mu = \text{Nc}‘\alpha$

Observe that when we have such a hypothesis as "$\mu \in \text{NC}$," the μ, though it may be of any type, must be of *some* type; hence the μ cannot have the typical ambiguity which belongs to $\text{Nc}‘\alpha$. If we put $\mu = \text{Nc}‘\alpha$, this will hold only in the type of μ; but "$\text{sm}“\mu$" is a typically ambiguous symbol, which will represent in any type the "same" number as μ. Thus "$\text{sm}“\mu = \text{Nc}‘\alpha$" is an equation which is applicable to all possible typical determinations of "sm" and "Nc."

$*100{\cdot}52$. $\vdash : \mu \in \text{NC} . \exists ! \mu . \supset . \text{sm}“\mu \in \text{NC}$

The hypothesis $\exists ! \mu$ is unnecessary, but we cannot prove this till later ($*102$).

We end the number with some propositions ($*100{\cdot}6$—$\cdot64$) stating that various classes (such as $\iota“\alpha$), which have already been proved to be similar to α, have $\text{Nc}‘\alpha$ members.

***100·22.** $\vdash . \mathrm{Nc} \in 1 \to \mathrm{Cls} \quad [*72{\cdot}12 . (*100{\cdot}01)]$

***100·3.** $\vdash . \alpha \in \mathrm{Nc}‘\alpha \quad [*73{\cdot}3 . *100{\cdot}1]$

Note that it is fallacious to infer $\exists\,!\, \mathrm{Nc}‘\alpha$, for reasons explained in the introduction to the present section.

***100·31.** $\vdash : \alpha \in \text{Nc}`\beta . \equiv . \beta \in \text{Nc}`\alpha . \equiv . \alpha \,\text{sm}\, \beta$ [*32·18 . *73·31 . (*100·01)]

***100·32.** $\vdash : \alpha \in \text{Nc}`\beta . \beta \in \text{Nc}`\gamma . \supset . \alpha \in \text{Nc}`\gamma$ [*100·31 . *73·32]

***100·321.** $\vdash : \alpha \,\text{sm}\, \beta . \supset . \text{Nc}`\alpha = \text{Nc}`\beta$

Dem.

$\vdash . *73 \cdot 37 . \supset \vdash :. \text{Hp} . \supset : \gamma \,\text{sm}\, \alpha . \equiv_\gamma . \gamma \,\text{sm}\, \beta :$

[*100·1] $\supset : \text{Nc}`\alpha = \text{Nc}`\beta :. \supset \vdash . \text{Prop}$

Note that $\text{Nc}`\alpha = \text{Nc}`\beta . \supset . \alpha \,\text{sm}\, \beta$ is not always true. We might be tempted to prove it as follows:

$\vdash . *100 \cdot 1 . \supset \vdash :. \text{Nc}`\alpha = \text{Nc}`\beta . \equiv : \gamma \,\text{sm}\, \alpha . \equiv_\gamma . \gamma \,\text{sm}\, \beta :$

[*10·1] $\supset : \alpha \,\text{sm}\, \alpha . \equiv . \alpha \,\text{sm}\, \beta :$

[*73·3] $\supset : \alpha \,\text{sm}\, \beta$

But the use of *10·1 here is only legitimate when the "sm" concerned is a homogeneous relation. If $\text{Nc}`\alpha$, $\text{Nc}`\beta$ are descending cardinals, we may have $\text{Nc}`\alpha = \Lambda = \text{Nc}`\beta$ without having $\alpha \,\text{sm}\, \beta$.

***100·33.** $\vdash : \exists ! \text{Nc}`\alpha \cap \text{Nc}`\beta . \supset . \alpha \,\text{sm}\, \beta$

Dem.

$\vdash . *100 \cdot 1 . \supset \vdash : \text{Hp} . \supset . (\exists \gamma) . \gamma \,\text{sm}\, \alpha . \gamma \,\text{sm}\, \beta .$

[*73·31] $\supset . (\exists \gamma) . \alpha \,\text{sm}\, \gamma . \gamma \,\text{sm}\, \beta .$

[*73·32] $\supset . \alpha \,\text{sm}\, \beta : \supset \vdash . \text{Prop}$

Note that we do not always have

$$\alpha \,\text{sm}\, \beta . \supset . \exists ! \text{Nc}`\alpha \cap \text{Nc}`\beta .$$

For if the Nc concerned is a descending Nc, and α and β are sufficiently great, $\text{Nc}`\alpha$ and $\text{Nc}`\beta$ may both be Λ. For example, we have

$$\text{Cl}`(\alpha \cup - \alpha) \,\text{sm}\, \text{Cl}`(\alpha \cup - \alpha).$$

But $\text{Nc}\,(\alpha)`\text{Cl}`(\alpha \cup - \alpha) = \Lambda$, so that

$$\sim \exists ! \text{Nc}\,(\alpha)`\text{Cl}`(\alpha \cup - \alpha) \cap \text{Nc}\,(\alpha)`\text{Cl}`(\alpha \cup - \alpha).$$

Thus "$\alpha \,\text{sm}\, \beta . \supset . \exists ! \text{Nc}`\alpha \cap \text{Nc}`\beta$" is not always true when it is significant.

***100·34.** $\vdash : \exists ! \text{Nc}`\alpha \cap \text{Nc}`\beta . \supset . \text{Nc}`\alpha = \text{Nc}`\beta$ [*100·33·321]

***100·35.** $\vdash :. \exists ! \text{Nc}`\alpha . \vee . \exists ! \text{Nc}`\beta : \supset :$

$$\text{Nc}`\alpha = \text{Nc}`\beta . \equiv . \alpha \in \text{Nc}`\beta . \equiv . \beta \in \text{Nc}`\alpha . \equiv . \alpha \,\text{sm}\, \beta$$

Dem.

$\vdash . *22 \cdot 5 . \quad \supset \vdash :. \text{Hp} . \supset : \text{Nc}`\alpha = \text{Nc}`\beta . \supset . \exists ! \text{Nc}`\alpha \cap \text{Nc}`\beta .$

[*100·33] $\supset . \alpha \,\text{sm}\, \beta$ (1)

$\vdash . (1) . *100 \cdot 321 . \supset \vdash :. \text{Hp} . \supset : \text{Nc}`\alpha = \text{Nc}`\beta . \equiv . \alpha \,\text{sm}\, \beta$ (2)

$\vdash . (2) . *100 \cdot 31 . \supset \vdash . \text{Prop}$

Thus the only case in which the implications in *100·321·33·34 cannot be turned into equivalences is the case in which $\text{Nc}`\alpha$ and $\text{Nc}`\beta$ are both Λ.

***100·36.** $\vdash :. \beta \in \text{Nc}`\alpha . \supset : \exists ! \alpha . \equiv . \exists ! \beta$ [*100·31 . *73·36]

*101. ON 0 AND 1 AND 2

Summary of *101.

In the present number, we have to show that 0 and 1 and 2 as previously defined are cardinal numbers in the sense defined in *100, and to add a few elementary propositions to those already given concerning them. We prove (*101·12·241) that 0 and 1 are not null, which cannot be proved, with our axioms, for any other cardinal, except (in the case of finite cardinals) when the type is specified as a sufficiently high one. Thus we prove (*101·42·43) that 2_{Cls} and 2_{Rel} exist; this follows from $\Lambda \neq V$ and $\dot{\Lambda} \neq \dot{V}$. We prove (*101·22·34) that 0 and 1 and 2 are all different from each other. We prove (*101·15·28) that $\mathrm{sm}``0 = 0$ and $\mathrm{sm}``1 = 1$, but we cannot prove $\mathrm{sm}``2 = 2$ unless we assume the existence of at least two individuals, or define the first 2 in "$\mathrm{sm}``2 = 2$" as a 2 of some type other than 2_{Indiv}, where "Indiv" stands for the type of individuals.

It should be observed that, since 0 and 1 and 2 are typically ambiguous, their properties are analogous to those of "$\mathrm{Nc}`\alpha$" rather than to those of μ, where $\mu \in \mathrm{NC}$. For example, we have

***100·511.** $\vdash : \exists ! \, \mathrm{Nc}`\beta \, . \supset . \, \mathrm{sm}``\mathrm{Nc}`\beta = \mathrm{Nc}`\beta$

but we shall not have $\mu \in \mathrm{NC} \, . \exists ! \, \mu \, . \supset . \, \mathrm{sm}``\mu = \mu$ unless the "sm" concerned is homogeneous, since in other cases the symbols do not express a significant proposition. But in *100·511 we may substitute 0 or 1 or 2, and the proposition remains significant and true. In fact we have (*101·1·2·31)

$$\vdash . \, 0 = \mathrm{Nc}`\Lambda \, . \, 1 = \mathrm{Nc}`\iota`x \, . \, 2 = \mathrm{Nc}`(\iota`\iota`x \cup \iota`\Lambda),$$

where 0 and 1 and 2 have an ambiguity corresponding to that of "Nc."

$*102$. ON CARDINAL NUMBERS OF ASSIGNED TYPES

Summary of $*102$.

In this number, we shall consider a typically definite relation "Nc," *i.e.* we shall consider the relation, to a class δ which is given as of the same type as β, of the class μ of those classes γ which are similar to δ and of the same type as α. We shall then put

$$\mu = \mathrm{Nc}\,(\alpha_\beta)\text{‘}\delta,$$
$$\gamma \,\epsilon\, \mathrm{Nc}\,(\alpha_\beta)\text{‘}\delta,$$
$$\gamma \,\mathrm{sm}_{(\alpha,\,\beta)}\,\delta,$$

and the class of all such numbers as μ for a given α and β we shall call $\mathrm{NC}^\beta\,(\alpha)$, so that

$$\mathrm{NC}^\beta\,(\alpha) = \mathrm{D}\text{‘}\mathrm{Nc}\,(\alpha_\beta).$$

The notations here introduced for giving typical definiteness to "sm" and "Nc" are those defined in $*65$ for any typically ambiguous relation.

By $*63{\cdot}01{\cdot}02$ we have, if α is a typically ambiguous symbol,

$$\vdash .\, \alpha_x = \alpha \cap t\text{‘}x,$$
$$\vdash .\, \alpha\,(x) = \alpha \cap t\text{‘}\iota\text{‘}x.$$

Thus $\vdash .\, \alpha\,(x) = \alpha_{\iota\text{‘}x}$. If we apply the definitions to 1, "1_x" is meaningless unless x is a class; we therefore write a Greek letter in place of x, and we have

$$\vdash .\, 1_\beta = 1 \cap t\text{‘}\beta = 1 \cap (\iota\text{‘}\beta \cup -\iota\text{‘}\beta).$$

If $x \,\epsilon\, \beta$, we shall have $\iota\text{‘}x = \beta \,.\vee.\, \iota\text{‘}x \neq \beta$. Hence

$$\vdash : x \,\epsilon\, \beta \,.\supset.\, \iota\text{‘}x \,\epsilon\, 1_\beta.$$

Similarly $\qquad \vdash : x \sim\epsilon\, \beta \,.\supset.\, \iota\text{‘}x \,\epsilon\, 1_\beta.$

Thus $\qquad \vdash : x \,\epsilon\, t_0\text{‘}\beta \,.\supset.\, \iota\text{‘}x \,\epsilon\, 1_\beta.$

The converse implication also holds, so that

$$\vdash : x \,\epsilon\, t_0\text{‘}\beta \,.\equiv.\, \iota\text{‘}x \,\epsilon\, 1_\beta.$$

Thus 1_β consists of all unit classes whose sole members x either are or are not members of β, *i.e.* for which "$x \,\epsilon\, \beta$" is significant.

In "$x \,\epsilon\, t_0\text{‘}\beta \,.\supset.\, \iota\text{‘}x \,\epsilon\, 1_\beta$," the hypothesis renders explicit the condition of significance; thus "$\iota\text{‘}x \,\epsilon\, 1_\beta$" is always true when significant, and always significant when $x \,\epsilon\, t_0\text{‘}\beta$. On the interpretation of negative statements concerning types, see the note at the end of this number.

It should be noted that all the constant relations introduced in this work are typically ambiguous. Consider *e.g.* $\dot\Lambda$, sg, D, s, $\dot s$, I, ι, ϵ, Cl, Rl. These all have more or less typical ambiguity, though all of them have what we will call *relative* typical definiteness, *i.e.* when the type of the relatum is given, that of the referent is given also. (In regard to D, it is not true that, conversely

when the type of the referent is given, that of the relatum is also given.) But "sm" and "Nc" have not even relative definiteness. When the type of the relatum is given, that of the referent becomes no more definite than before; the only restrictions are that the relatum for "sm" or "Nc" must be a class, that the referent for "sm" must be a class, and that the referent for "Nc" must be a class of classes. When a relation R has relative definiteness, it is enough to fix the type of the relatum; and if further $R \epsilon 1 \rightarrow \mathrm{Cls}$, so that R leads to a descriptive function, "$R`y$" has complete typical definiteness as soon as the type of y is given. Now the constant relations hitherto introduced, with the exception of "sm" and "$\dot{\mathrm{V}}$," have all been one-many relations, and have been used almost exclusively in the form of descriptive functions. Hence no special notation has been required to give typical definiteness, since "$R`y$," in these circumstances, has typical definiteness as soon as $y$ is assigned. But with the consideration of "sm" and "Nc," which do not have even relative definiteness, an explicit means of giving typical definiteness becomes necessary. It should be observed, however, that "$\mathrm{Nc}`\delta$" has typical definiteness, when δ is known, as soon as the *domain* of "Nc" has typical definiteness, since δ must belong to the converse domain. It is for the sake of this and similar cases that we introduced the two definitions in $*65$, which only give typical definiteness to the *domain*.

In virtue of the definitions in $*65$, if R is a typically ambiguous relation, and x is a referent, R becomes R_x; if, further, y is a relatum, R becomes $R_{(x,y)}$. If x is a referent for R, we have $(\exists y) \,.\, x \epsilon \overrightarrow{R}`y$, and $\overrightarrow{R}`y \epsilon \mathrm{D}`\overrightarrow{R}$. Thus $\mathrm{D}`\overrightarrow{R}$ has a member of the type next above that of x, *i.e.* of the type of $\iota`x$. Thus

$$\vdash \,.\, \mathrm{sg}`(R_x) = (\overrightarrow{R})(x)$$

and

$$\vdash \,.\, \mathrm{sg}`\{R_{(x,y)}\} = (\overrightarrow{R})(x_y)$$

as was proved in $*65$. Hence in particular

$$\vdash \,.\, \mathrm{sg}`\{\mathrm{sm}_{(\alpha,\beta)}\} = \mathrm{Nc}\,(\alpha_\beta).$$

It is chiefly for this reason that it is worth while to introduce the definition of $R\,(x_y)$.

We have, in virtue of the above, as will be proved in $*102{\cdot}46$,

$$\vdash : \gamma \epsilon t`\alpha \,.\, \delta \epsilon t`\beta \,.\, \gamma \,\mathrm{sm}\, \delta \,.\equiv .\, \gamma \epsilon \mathrm{Nc}\,(\alpha_\beta)`\delta.$$

With regard to "$\mathrm{Nc}\,(\alpha)$," which is to be interpreted by $*65{\cdot}04$, some caution is necessary. This will mean *some one* of those typically different relations called "Nc" which have their domains composed of terms of the same type as α. But it will not mean the logical sum of all such relations, because these relations are of different types according as their converse domains differ in type, and therefore their logical sum is meaningless. Thus for example if the type of β is lower than or equal to that of α, we shall have

$$\vdash \,.\, \exists !\, \mathrm{Nc}\,(\alpha)`\beta,$$

whence, if "Nc (α)" has its converse domain composed of terms of the same type as β,

$$\vdash . \Lambda \sim\epsilon \text{D}'\text{Nc}(\alpha).$$

But if β is of higher type than α, we shall find

$$\vdash . \Lambda \epsilon \text{D}'\text{Nc}(\alpha).$$

Thus "Nc (α)" is indeterminate in a way that makes a practical difference.

Exactly similar remarks apply to NC (α). We have

$$\vdash . \text{NC}(\alpha) = \text{D}'\text{Nc}(\alpha);$$

thus "NC (α)" shares the ambiguity of "Nc (α)." The question whether $\Lambda \epsilon \text{NC}(\alpha)$ depends upon the decision of this ambiguity. The difficulty is that "NC (α)" stands for the domain of any one determination of "Nc" which has its domain composed of objects of the type of $\iota'\alpha$; but it is the domain of *only one* such determination of "Nc," because different determinations are of different types, and therefore cannot be taken together, even when their domains are all of the same type. In consequence of this ambiguity, "NC (α)" is a symbol which is as a rule better avoided, and "Nc (α)" is not often useful except as a descriptive function, in which case the relatum supplies the requisite typical definiteness.

The peculiarity of "NC (α)" is that it is *typically* definite, and yet is capable of different meanings: it is not *wholly* definite, being defined as the domain of a relation whose converse domain is typically ambiguous. It results that we cannot profitably make "NC" half-definite, as "NC (α)" does, but must make it completely definite, as we do by taking $\text{D}'\text{Nc}(\alpha_\beta)$. For this we adopt the notation $\text{NC}^\beta(\alpha)$. We cannot adopt the notation $\text{NC}(\alpha_\beta)$, because that would conflict with $*65{\cdot}11$, nor $\text{NC}(\alpha)_\beta$, because that would conflict with $*65{\cdot}01$, nor $\text{NC}_\beta(\alpha)$, for the same reason. But $\text{NC}^\beta(\alpha)$ has no previously defined meaning. We may if we like regard "NC^β" as $\text{D}'(\text{Nc} \upharpoonright t'\beta)$. Then the required meaning of "$\text{NC}^\beta(\alpha)$" would result from $*65{\cdot}04$. But as "NC^β" so defined is not required, it is simpler to regard "$\text{NC}^\beta(\alpha)$" as a single symbol. We therefore put

$*102{\cdot}01$. $\text{NC}^\beta(\alpha) = \text{D}'\text{Nc}(\alpha_\beta)$ Df

The present number begins with various propositions ($*102{\cdot}2$—$\cdot27$) on a typically definite relation of similarity, *i.e.* $\text{sm}_{(\alpha,\beta)}$. We then have a set of propositions ($*102{\cdot}3$—$\cdot46$) on "$\text{Nc}(\alpha_\beta)'\delta$." This is only significant if β and δ are of the same type; it then denotes the class of those classes which are similar to δ and of the same type as α. We then have a set of propositions ($*102{\cdot}5$—$\cdot64$) on $\text{NC}^\beta(\alpha)$, *i.e.* on cardinals consisting of classes of the same type as α which are similar to classes of the same type as β. We next prove ($*102{\cdot}71$—$\cdot75$) that no sub-class of α is similar to $\text{Cl}'\alpha$, and therefore (substituting $t_0'\alpha$ for α) no class of the same type as α is similar to $t'\alpha$, and therefore

$*102{\cdot}74$. $\vdash . \Lambda \epsilon \text{NC}^{t'\alpha}(\alpha)$

This proves that Λ is a cardinal, which is a proposition constantly required. The remaining propositions of $*102$ are concerned with $\mathrm{sm}``\mu$ where μ is a typically definite cardinal.

The most useful propositions in this number (apart from $*102\cdot74$) are

$*102\cdot3$. $\vdash : \gamma \,\mathrm{sm}_{(\alpha,\beta)}\, \delta \,.\equiv.\, \gamma \in \mathrm{Nc}\,(\alpha_\beta)`\delta$

$*102\cdot46$. $\vdash : \gamma \in \mathrm{Nc}\,(\alpha_\beta)`\delta \,.\doteq.\, \delta \in \mathrm{Nc}\,(\beta_\alpha)`\gamma \,.\equiv.\, \gamma \,\mathrm{sm}\, \delta \,.\, \gamma \in t`\alpha \,.\, \delta \in t`\beta$

$*102\cdot5$. $\vdash : \mu \in \mathrm{NC}^\beta\,(\alpha) \,.\equiv.\, (\exists\delta) \,.\, \mu = \mathrm{Nc}\,(\alpha_\beta)`\delta$

$*102\cdot6$. $\vdash .\, \mathrm{Nc}\,(\alpha)`\beta = \mathrm{Nc}\,(\alpha_\beta)`\beta = \hat{\gamma}\,(\gamma \,\mathrm{sm}\, \beta \,.\, \gamma \in t`\alpha) = \mathrm{Nc}`\beta \cap t`\alpha$

$*102\cdot72$. $\vdash : \beta \subset \alpha \,.\supset.\, \sim(\beta \,\mathrm{sm}\, \mathrm{Cl}`\alpha)$

This is used in proving $\mu \in \mathrm{NC} \,.\supset.\, 2^\mu > \mu$, which is the proposition from which Cantor deduced that there is no greatest cardinal. (If $\mu = \mathrm{Nc}`\alpha$, $2^\mu = \mathrm{Nc}`\mathrm{Cl}`\alpha$, and thus there is a rise of type.)

$*102\cdot84$. $\vdash : (\exists\gamma) \,.\, \gamma \,\mathrm{sm}\, \alpha \,.\, \gamma \in t`\alpha \,.\, \delta \,\mathrm{sm}\, \gamma \,.\equiv.\, \delta \,\mathrm{sm}\, \alpha$

$*102\cdot85$. $\vdash .\, \mathrm{sm}``\mu \cap t`\beta = \mathrm{sm}_\beta``\mu$

$*102\cdot01$. $\mathrm{NC}^\beta\,(\alpha) = \mathrm{D}`\mathrm{Nc}\,(\alpha_\beta)$ Df

$*102\cdot11$. $\vdash : R \in 1 \to 1 \,.\supset.\, R_{(x,y)} \in 1\,(x) \to 1\,(y)$

Here, if R is a real variable, the conditions of significance require $R = R_{(x,y)}$. But if R is a typically ambiguous constant, such as I or $\dot{\Lambda}$ or sg, $R_{(x,y)}$ is a typically definite constant. It is chiefly for such cases that propositions such as the above are useful.

The above proposition shows that, if every class of the same type as β is similar to some class of the same type as α, then, given a class γ of the same type as α, there is a class δ, of the same type as β, such that the classes similar to δ and of the same type as α are the same as the classes similar to γ and of

the same type as α; and conversely, given any class δ, of the same type as β, and similar to some class of the same type as α, then there is a class γ, of the same type as α, such that the classes similar to γ and of the same type as α are the same as the classes similar to δ and of the same type as α. We may express this by saying that, if the cardinals which go from the type of α to the type of β are never null, then those that go from the type of β to the type of α, with the exception of Λ (if Λ is one of them), are the same as those that begin and end within the type of α. The latter are what we call "homogeneous" cardinals. Thus our proposition is a step towards reducing the general study of cardinals to that of homogeneous cardinals.

This proposition proves that no class of the same type as α is similar to $t'\alpha$. Now $t'\alpha$ is the greatest class of its type; thus there are classes of the type next above that of α which are too great to be similar to any class of the type of α. Thus (as will be explicitly proved later) the maximum cardinal in one type is less than that in the next higher type. Cantor's proposition that there is no maximum cardinal only holds when we are allowed to rise to continually higher types: in each type, there is a maximum for that type, namely the number of members of the type.

$\vdash . (1) . *102·73 . \supset \vdash . \text{Prop}$

Note on negative statements concerning types. Statements such as "$x \sim \epsilon t`y$" or "$x \sim \epsilon t_0`\alpha$" are always false when they are significant. Hence when an object belongs to one type, there is no significant way of expressing what we mean when we say that it does not belong to some other type. The reason is that, when, for example, $t`\alpha$ and $t_0`\alpha$ are said to be different, the statement is only significant if interpreted as applying to the symbols, *i.e.* as meaning to deny that the two symbols denote the same class. We cannot assert that they denote *different* classes, since "$t`\alpha \neq t_0`\alpha$" is not significant, but we can deny that they denote the same class. Owing to this peculiarity, propositions dealing with types acquire their importance largely from the fact that they can be interpreted as dealing with the symbols rather than directly with the objects denoted by the symbols. Another reason for the importance of typically definite propositions is that, when they are implications of which the hypothesis can be asserted, they can be used for *inference*, *i.e.* for the assertion of the conclusion. Where typically ambiguous symbols occur in implications, on the contrary, the conditions of significance may be different for the hypothesis and the conclusion, so that fallacies may arise from the use of such implications in inference. *E.g.* it is fallacy to infer "$\vdash . \exists ! \mathrm{Nc}`\alpha$" from the (true) propositions "$\vdash : \alpha \epsilon \mathrm{Nc}`\alpha . \supset . \exists ! \mathrm{Nc}`\alpha$" and "$\vdash . \alpha \epsilon \mathrm{Nc}`\alpha$." (The truth of the first of these two requires that "$\mathrm{Nc}`\alpha$" should receive the same typical determination in both its occurrences.) For these two reasons hypotheticals concerning types are often useful, in spite of the fact that their hypotheses are always true when they are significant.

$*103$. HOMOGENEOUS CARDINALS

Summary of $*103$.

In this number, we shall consider cardinals generated by a homogeneous relation of similarity. A "homogeneous" cardinal is to mean all the classes similiar to some class α and of the same type as α. The "homogeneous cardinal of α" will be defined as $\mathrm{Nc}'\alpha \cap t'\alpha$; we shall denote it by "$\mathrm{N_0c}'\alpha$." Then the class of homogeneous cardinals is the class of all such cardinals as "$\mathrm{N_0c}'\alpha$," *i.e.* it is $\mathrm{D}'\mathrm{N_0c}$; this we shall denote by "$\mathrm{N_0C}$." The symbol "$\mathrm{N_0c}'\alpha$" is typically definite as soon as α is assigned; "$\mathrm{N_0C}$," on the contrary, is typically ambiguous: it must be a Cls^3, but otherwise its type may vary indefinitely. Homogeneous cardinals have, however, many properties which do not require that the ambiguity of "$\mathrm{N_0C}$" should be determined, and few which do require this. They are important also as being the simplest kind of cardinals, and as being a kind to which other kinds can usually be reduced.

The chief advantage of homogeneous cardinals is that they are never null ($*103{\cdot}13{\cdot}22$). This enables us to avoid by their means the explicit exclusion of exceptional cases; thus throughout Section B we shall use homogeneous cardinals in defining the arithmetical operations: the arithmetical sum of $\mathrm{Nc}'\alpha$ and $\mathrm{Nc}'\beta$, for example, will be defined by means of $\mathrm{N_0c}'\alpha$ and $\mathrm{N_0c}'\beta$, in order to exclude such a determination of the typical ambiguity of $\mathrm{Nc}'\alpha$ and $\mathrm{Nc}'\beta$ as would make either of them null. It is true that not only homogeneous cardinals, but also ascending cardinals (cf. $*104$), are never null. But homogeneous cardinals are much the simplest kind of cardinals that are never null, and are therefore the most convenient.

The fact that no homogeneous cardinal is null is derived from

$*103{\cdot}12$. $\vdash . \alpha \in \mathrm{N_0c}'\alpha$

Other important propositions in this number are the following:

$*103{\cdot}2$. $\vdash : \mu \in \mathrm{N_0C} . \equiv . (\exists\alpha) . \mu = \mathrm{Nc}'\alpha \cap t'\alpha . \equiv . (\exists\alpha) . \mu = \mathrm{N_0c}'\alpha$

$*103{\cdot}26$. $\vdash :. \mu \in \mathrm{NC} . \supset : \alpha \in \mu . \equiv . \mathrm{N_0c}'\alpha = \mu$

The above proposition is used constantly.

$*103{\cdot}27$. $\vdash : \mu = \mathrm{N_0c}'\alpha . \equiv . \mu \in \mathrm{NC} . \alpha \in \mu$

Thus to say that μ is the homogeneous cardinal of α is equivalent to saying that μ is a cardinal of which α is a member.

$\vdash . (1) . *102·5 . \supset \vdash . \text{Prop}$

In the above proposition, the "β" may be omitted, and we may write (cf. *103·33, below)

$$\vdash . \text{NC}(\alpha) - \iota`\Lambda \subset \text{N}_0\text{C}(\alpha).$$

For the β is wholly arbitrary, so that any possible determination of $\text{NC}(\alpha)$ makes the above proposition true. We may proceed a step further, and write (*103·34, below)

$$\vdash . \text{NC} - \iota`\Lambda \subset \text{N}_0\text{C}.$$

But although we also have $\text{N}_0\text{C} \subset \text{NC} - \iota`\Lambda$, provided the "NC" on the right is suitably determined, we do not have this always. For example, if "NC" is determined as $\text{NC}^\alpha(t`\alpha)$, and "$\text{N}_0\text{C}$" as $\text{N}_0\text{C}(t`\alpha)$, then $\text{N}_0\text{c}`t`\alpha \epsilon \text{N}_0\text{C} - \text{NC}$.

\end{aligned}$$

Thus every cardinal except Λ is a homogeneous cardinal in the appropriate type. Note that although of course every homogeneous cardinal is a cardinal, yet "$\mathrm{N}_0\mathrm{C} \subset \mathrm{NC}$" must not be asserted, because it is possible to determine the ambiguity of "NC" in such a way as to make this false. Hence we do not get $\mathrm{NC} - \iota\text{‘}\Lambda = \mathrm{N}_0\mathrm{C}$.

$*103{\cdot}35$. $\vdash : \Lambda \sim\in \mathrm{NC}^\alpha(\beta) . \supset . \mathrm{NC}^\beta(\alpha) - \iota\text{‘}\Lambda = \mathrm{N}_0\mathrm{C}(\alpha)$ [$*102{\cdot}55 . *103{\cdot}301$]

The hypothesis of this proposition is satisfied, as will appear later, if the type of β is in what we may call the direct ascent from that of α, *i.e.* if it can be reached from α by a finite number of steps each of which takes us from a type τ to either $\mathrm{Cl}\text{‘}\tau$ or $\mathrm{Rl}\text{‘}(\tau \uparrow \tau)$. Thus in such a case the cardinals (other than Λ) which go from $t\text{‘}\beta$ to $t\text{‘}\alpha$ are the same as those which begin and end within $t\text{‘}\alpha$. It will also appear that in such a case Λ always is a member of $\mathrm{NC}^\beta(\alpha)$. *If* two cardinals which are not equal must always be one greater and the other less, then $\Lambda \in \mathrm{NC}^\beta(\alpha)$ is the condition for $\mathrm{N}_0\mathrm{c}\text{‘}t\text{‘}\beta > \mathrm{Nc}(\beta)\text{‘}t\text{‘}\alpha$. In that case, we shall have $\Lambda \in \mathrm{NC}^\beta(\alpha) . \supset . \Lambda \sim\in \mathrm{NC}^\alpha(\beta)$. But there is no known proof that of two different cardinals one must be the greater, except by assuming the multiplicative axiom and proving thence (by Zermelo's theorem) that every class can be well-ordered (cf. $*258$).

0 and 1 are the only cardinals of which the above property can be proved universally with our assumptions. If (as is possible so far as our assumptions go) the lowest type is a unit class, we shall have *in that type* (though in no other) $2 = \Lambda$, so that in that type $2 \sim\epsilon \mathrm{N_0C}$.

$*104$. ASCENDING CARDINALS

Summary of $*104$.

In this number we have to consider cardinals derived from a relation of similarity which goes from the type of α to that of $t`\alpha$, or to that of $t^2`\alpha$. The propositions to be proved can be extended, by a mere repetition of the proofs, to $t^3`\alpha$, $t^4`\alpha$, etc. This extension must, however, be made afresh in each instance; we cannot prove that it can be made generally, because mathematical induction cannot be applied to the series

$$t_0`\alpha,\ t`\alpha,\ t^2`\alpha,\ t^3`\alpha,\ \ldots.$$

Ascending cardinals, though less important than homogeneous cardinals, yet have considerable importance in arithmetic, because $\mathrm{Nc}`\alpha \times \mathrm{Nc}`\beta$ and $(\mathrm{Nc}`\alpha)^{\mathrm{Nc}`\beta}$ are defined as the cardinals of classes of higher types than those of α and β, and the same applies to the product of the cardinals of members of a class of classes. In these cases, however, we also need cardinals of relational types, which will be dealt with in $*106$.

We have to deal, in this number, with three different sets of notions, namely

$*104\cdot01$. $\mathrm{N}^1\mathrm{c}`\alpha = \mathrm{Nc}`\alpha \cap t`t`\alpha$ Df

$*104\cdot02$. $\mathrm{N}^1\mathrm{C} = \mathrm{D}`\mathrm{N}^1\mathrm{c}$ Df

$*104\cdot03$. $\mu^{(1)} = \mathrm{sm}``\mu \cap t`\mu$ Df

with similar definitions of $\mathrm{N}^2\mathrm{c}`\alpha$, etc. Thus $\mathrm{N}^1\mathrm{c}`\alpha$ consists of all classes similar to α but of the next higher type, *i.e.* it is the cardinal number of α in the type next above that of $\mathrm{N}_0\mathrm{c}`\alpha$; $\mathrm{N}^1\mathrm{C}$ is the class of all such cardinals as $\mathrm{N}^1\mathrm{c}`\alpha$, and is a typically ambiguous symbol, though $\mathrm{N}^1\mathrm{c}`\alpha$ is typically definite when α is given; $\mu^{(1)}$ (if μ is a cardinal which is not null) is the "same" cardinal in the next higher type, so that, *e.g.*, if μ is 1 determined as consisting of unit classes of *individuals*, $\mu^{(1)}$ will be 1 determined as consisting of unit classes of classes of individuals. (When μ is not an existent cardinal, $\mu^{(1)}$ is unimportant.)

The following are the most useful propositions in the present number:

$*104\cdot12$. $\vdash : \beta \in \mathrm{N}^1\mathrm{c}`\alpha \,.\, \gamma \in \mathrm{N}^1\mathrm{c}`\beta \,.\supset .\, \gamma \in \mathrm{N}^2\mathrm{c}`\alpha$

$*104\cdot2$. $\vdash . \iota``\alpha \in \mathrm{N}^1\mathrm{c}`\alpha$

$*104\cdot21$. $\vdash . \exists ! \mathrm{N}^1\mathrm{c}`\alpha$

$*104\cdot24$. $\vdash : \mu = \mathrm{N}^1\mathrm{c}`\alpha \,.\supset .\, \mu = \mathrm{N}_0\mathrm{c}`\iota``\alpha = \mathrm{N}_0\mathrm{c}`\hat{\beta}\{(\exists y) \,.\, y \in \alpha \,.\, \beta = \iota`x \cup \iota`y\}$

$*104.25$. $\vdash . \mathrm{N}^1\mathrm{C} \subset \mathrm{N}_0\mathrm{C}$

$*104\cdot26$. $\vdash : \mu = \mathrm{N}_0\mathrm{c}`\alpha \,.\supset .\, \mu^{(1)} = \mathrm{N}_0\mathrm{c}`\iota``\alpha = \mathrm{N}^1\mathrm{c}`\alpha$

$*104\cdot265$. $\vdash . \mu^{(1)} = \mathrm{sm}_\mu``\mu$

$*104\cdot27.\ \vdash :. \mu \in \mathrm{NC} . \supset : \mu = \mathrm{N_0c}`\alpha . \equiv . \mu^{(1)} = \mathrm{N^1c}`\alpha$

$*104\cdot35.\ \vdash . \mathrm{N^2C} \subset \mathrm{N^1C} . \mathrm{N^2C} \subset \mathrm{N_0C}$

$*104\cdot43.\ \vdash : t`\alpha = t`\beta . \supset . (\exists \gamma, \delta) . \gamma \in \mathrm{N^1c}`\alpha . \delta \in \mathrm{N^1c}`\beta . \gamma \cap \delta = \Lambda$

$*104\cdot01.\ \mathrm{N^1c}`\alpha = \mathrm{Nc}`\alpha \cap t`t`\alpha \quad \mathrm{Df}$

This defines the cardinal number of α in the next type above that of $\mathrm{N_0c}`\alpha$; thus $\mathrm{N^1c}`\alpha$ consists of all classes similar to α and of the next type above that of α.

$*104\cdot011.\ \mathrm{N^2c}`\alpha = \mathrm{Nc}`\alpha \cap t`t^2`\alpha \quad \mathrm{Df}$

Similar definitions are to be assumed for $\mathrm{N^3c}`\alpha$, etc.

$*104\cdot02.\ \mathrm{N^1C} = \mathrm{D}`\mathrm{N^1c} \quad \mathrm{Df}$

$\mathrm{N^1C}$, like $\mathrm{N_0C}$, is typically ambiguous; but $\mathrm{N^1C}(\alpha)$ is typically definite.

$*104\cdot021.\ \mathrm{N^2C} = \mathrm{D}`\mathrm{N^2c} \quad \mathrm{Df}$

Similar definitions are to be assumed for $\mathrm{N^3C}$, etc.

$*104\cdot03.\ \mu^{(1)} = \mathrm{sm}``\mu \cap t`\mu \quad \mathrm{Df}$

Here, if μ is a cardinal, $\mu^{(1)}$ is the same cardinal in the next higher type. For example, if μ is couples of individuals, $\mu^{(1)}$ is couples of classes of individuals.

$*104\cdot031.\ \mu^{(2)} = \mathrm{sm}``\mu \cap t^2`\mu \quad \mathrm{Df}$

Similar definitions are to be assumed for $\mu^{(3)}$, etc.

$*104\cdot1.\ \vdash : \beta \in \mathrm{N^1c}`\alpha . \equiv . \beta \in \mathrm{Nc}`\alpha . \beta \in t`t`\alpha . \equiv . \beta \in \mathrm{Nc}`\alpha . \beta \subset t`\alpha$

$*104{\cdot}01.\quad N^1c`\alpha = Nc`\alpha \cap t`t`\alpha \qquad Df$

This defines the cardinal number of α in the next type above that of $N_0c`\alpha$; thus $N^1c`\alpha$ consists of all classes similar to α and of the next type above that of α.

$*104{\cdot}011.\quad N^2c`\alpha = Nc`\alpha \cap t`t^2`\alpha \qquad Df$

Similar definitions are to be assumed for $N^3c`\alpha$, etc.

$*104{\cdot}02.\quad N^1C = D`N^1c \qquad Df$

N^1C, like N_0C, is typically ambiguous; but $N^1C(\alpha)$ is typically definite.

$*104{\cdot}021.\quad N^2C = D`N^2c \qquad Df$

Similar definitions are to be assumed for N^3C, etc.

$*104{\cdot}03.\quad \mu^{(1)} = sm``\mu \cap t`\mu \qquad Df$

Here, if μ is a cardinal, $\mu^{(1)}$ is the same cardinal in the next higher type. For example, if μ is couples of individuals, $\mu^{(1)}$ is couples of classes of individuals.

$*104{\cdot}031.\quad \mu^{(2)} = sm``\mu \cap t^2`\mu \qquad Df$

Similar definitions are to be assumed for $\mu^{(3)}$, etc.

$*104{\cdot}1.\quad \vdash : \beta \in N^1c`\alpha . \equiv . \beta \in Nc`\alpha . \beta \in t`t`\alpha . \equiv . \beta \in Nc`\alpha . \beta \subset t`\alpha$

∗104·141. $\vdash : \mu \in \mathrm{NC} \,.\, \exists ! \mu \,.\supset .\, \mu^{(1)} \in \mathrm{NC} \quad [{*}100{\cdot}52]$

When the hypothesis "$\exists ! \mu$" is omitted, this proposition is still true, but with a difference. *E.g.* let us put

$$\mu = \mathrm{Nc}\,(\alpha)\text{‘}t\text{‘}\alpha.$$

Then $\mu = \Lambda \,.\, \mu^{(1)} = \Lambda$. Thus $\mu^{(1)} \neq \mathrm{Nc}\,(t\text{‘}\alpha)\text{‘}t\text{‘}\alpha$. But we still have

$$\mu^{(1)} = \mathrm{Nc}\,(t\text{‘}\alpha)\text{‘}t^2\text{‘}\alpha.$$

Thus $\mu^{(1)} \in \mathrm{NC}$, but $\mu^{(1)}$ is not the same cardinal as μ in a higher type, *i.e.* there are classes whose cardinal in one type is μ, but whose cardinal in the next higher type is not $\mu^{(1)}$.

$\vdash . (1) . *104\cdot123 . \supset \vdash .$ Prop

The following propositions are concerned with the proof that, given any two cardinals μ and ν, of the same type, we can find two mutually exclusive classes one of which has μ terms while the other has ν terms. The proof requires that we should raise the types of both μ and ν one degree above that in which they were originally given, *i.e.* that we should turn μ and ν into $\mu^{(1)}$ and $\nu^{(1)}$. Thus, for example, suppose the total number of individuals in the universe were finite (a supposition which is consistent with our primitive propositions), and suppose μ were this number. Then unless $\nu = 0$, a class of ν individuals will be an existent sub-class of the only class which consists of μ individuals, and therefore we shall have

$$\alpha \epsilon \mu . \beta \epsilon \nu . \supset_{\alpha,\beta} . \exists ! \alpha \cap \beta .$$

But if we consider classes of μ *classes* and ν *classes*, we shall always be able to find a γ and a δ such that

$$\gamma \epsilon \mu^{(1)} . \delta \epsilon \nu^{(1)} . \gamma \cap \delta = \Lambda .$$

The existence of such a γ and δ is important in connection with the arithmetical operations, and is therefore proved here.

$*105$. DESCENDING CARDINALS

Summary of $*105$.

In this number, we consider cardinals generated by a relation of similarity which goes from a higher to a lower type, *i.e.* given any class of classes κ, we consider $\text{Nc}'\kappa$ in the type of members of κ (which we shall call $\text{N}_1\text{c}'\kappa$) or in some lower type. Thus *e.g.* we shall have

$$\kappa = \iota``\alpha \,.\, \supset \,.\, \alpha \in \text{N}_1\text{c}'\kappa,$$

where "$\text{N}_1\text{c}'\kappa$" means "classes similar to κ but of the next lower type." Similarly

$$\kappa = \iota``\iota``\alpha \,.\, \supset \,.\, \alpha \in \text{N}_2\text{c}'\kappa,$$

and so on. We shall have generally

$$\beta \in \text{N}_1\text{c}'\alpha \,.\, \equiv \alpha \in \text{N}^1\text{c}'\beta,$$

$$\beta \in \text{N}_2\text{c}'\alpha \,.\, \equiv \alpha \in \text{N}^2\text{c}'\beta,$$

and so on. The chief difference between ascending and descending cardinals is that Λ is one of the latter, but not one of the former. Otherwise the propositions of the present number are mostly analogous to corresponding propositions of $*104$.

On the analogy of the definitions in $*104$, we put

$$\text{N}_1\text{C} = \text{D}'\dot{\text{N}}_1\text{c} \qquad \text{Df},$$

$$\mu_{(1)} = \text{sm}``\mu \cap t_1{}'\mu \quad \text{Df},$$

with similar definitions for N_2C and $\mu_{(2)}$.

No proposition of the present number is ever referred to in the sequel, and the reader who is not interested in the subject may therefore omit it without detriment to what follows. The principal propositions proved are the following:

$*105\cdot25$. $\vdash \,.\, \text{N}_0\text{C} = \text{N}_1\text{C} - \iota'\Lambda$

$*105\cdot251$. $\vdash \,.\, \text{N}_0\text{C} = \text{N}_2\text{C} - \iota'\Lambda$

$*105\cdot26$. $\vdash \,.\, \text{N}_1\text{c}'t'\alpha = \Lambda$

Thus N_1C or N_2C, in any given type, only differs from N_0C in that type by the addition of Λ.

$*105\cdot3$. $\vdash : \mu = \text{N}_0\text{c}'\alpha \,.\, \supset \,.\, \mu_{(1)} = \text{N}_1\text{c}'\alpha$

$*105\cdot322$. $\vdash :. \exists ! \,\text{N}_1\text{c}'\alpha \,.\, \supset : \text{N}_1\text{c}'\alpha = \text{N}_1\text{c}'\beta \,.\, \equiv \,.\, \text{N}_0\text{c}'\alpha = \text{N}_0\text{c}'\beta$

$*105\cdot34$. $\vdash :. \mu \in \text{NC} \,.\, \exists ! \,\mu_{(1)} \,.\, \supset : \mu_{(1)} = \text{N}_1\text{c}'\alpha \,.\, \equiv \,.\, \mu = \text{N}_0\text{c}'\alpha$

$*105\cdot35$. $\vdash :. \mu \in \text{NC} \,.\, \nu \in \text{N}_0\text{C} \,.\, \supset : \mu = \nu^{(1)} \,.\, \equiv \,.\, \mu_{(1)} = \nu$

$*105\cdot38$. $\vdash \,.\, \{\mu_{(1)}\}_{(1)} = \mu_{(2)}$

$*105{\cdot}01.\quad N_1c`\alpha = Nc`\alpha \cap t`t_1`\alpha \quad Df$

We might write

$$N_1c`\alpha = Nc`\alpha \cap t_0`\alpha \quad Df,$$

which would be equivalent to the above. But we choose the above form for the sake of uniformity. If s is any suffix, we put, provided $t_s`\alpha$ has been defined

$$N_sc`\alpha = Nc`\alpha \cap t`t_s`\alpha \quad Df,$$

and if i is any index for which $t^i`\alpha$ has been defined, we put

$$N^ic`\alpha = Nc`\alpha \cap t`t^i`\alpha \quad Df.$$

Thus for the sake of uniformity it is better, in the above definition $*105{\cdot}01$ to write "$t`t_1`\alpha$" rather than "$t_0`\alpha$."

$*106$. CARDINALS OF RELATIONAL TYPES

Summary of $*106$.

In this number we have to consider the cardinals whose members are classes of relations which have a given relation of type to some given class. For example, we have $\downarrow x``\alpha \operatorname{sm} \alpha$, and $\downarrow x``\alpha$ has a given relation of type to α when x is given. Thus we want a notation for

$$\operatorname{Nc}`\alpha \cap t`\downarrow x``\alpha$$

and all the associated ideas. In this number, we shall deal only with relations in which the referent and relatum have a relation, as to type, which can be expressed by the notations of $*63$, *i.e.* roughly speaking, when, for suitable values of α, m, n, our relations are contained in

$$t^m`\alpha \uparrow t^n`\alpha \text{ or } t_m`\alpha \uparrow t_n`\alpha \text{ or } t^m`\alpha \uparrow t_n`\alpha \text{ or } t_m`\alpha \uparrow t^n`\alpha.$$

Thus if $t_{\mu\nu}`\alpha$ has been defined, we shall put

$$\mathrm{N}_{\mu\nu}\mathrm{c}`\alpha = \operatorname{Nc}`\alpha \cap t`t_{\mu\nu}`\alpha \quad \mathrm{Df},$$
$$\mathrm{N}_{\mu\nu}\mathrm{C} = \mathrm{D}`\mathrm{N}_{\mu\nu}\mathrm{c} \quad \mathrm{Df},$$
$$\xi_{(\mu\nu)} = \operatorname{sm}``\xi \cap t`t_{\mu\nu}`t_1`\xi \quad \mathrm{Df},$$

with analogous definitions for $t^{\mu\nu}`\alpha$, $t^{\mu}{}_{\nu}`\alpha$ and ${}^{\mu}t_{\nu}`\alpha$.

Much the most important case is that of $t_{00}`\alpha$. For this case we have

$*106\cdot1$. $\vdash : \beta \in \mathrm{N}_{00}\mathrm{c}`\alpha . \equiv . \beta \in \operatorname{Nc}`\alpha . \beta \in t`t_{00}`\alpha . \equiv . \beta \operatorname{sm} \alpha . \beta \in t`t`(t_0`\alpha \uparrow t_0`\alpha) .$
$\equiv . \beta \operatorname{sm} \alpha . \beta \subset t`(\alpha \uparrow \alpha)$

Thus $\mathrm{N}_{00}\mathrm{c}`\alpha$ will be the number of a class of relations whose fields are of the same type as $\alpha$, provided this class of relations is similar to $\alpha$. *E.g.* the number of terms such as $x \downarrow x$, where $x \in \alpha$, will be $\mathrm{N}_{00}\mathrm{c}`\alpha$.

We have

$*106\cdot21$. $\vdash . \exists ! \mathrm{N}_{00}\mathrm{c}`\alpha . \mathrm{N}_{00}\mathrm{c}`\alpha \in \mathrm{N}_0\mathrm{C}$

$*106\cdot22$. $\vdash : \lambda \in \mathrm{N}_0{}^1\mathrm{c}`\alpha . \equiv . \operatorname{Cnv}``\lambda \in {}^1\mathrm{N}_0\mathrm{c}`\alpha$

$*106\cdot23$. $\vdash : \beta \in \mathrm{N}^1\mathrm{c}`\alpha . \supset . \mathrm{N}^{11}\mathrm{c}`\alpha = \mathrm{N}_{00}\mathrm{c}`\beta$

$*106\cdot32$. $\vdash : t_0`\alpha = t_0`\beta . \supset . (\exists \gamma, \delta) . \gamma \in \mathrm{N}_{00}\mathrm{c}`\alpha . \delta \in \mathrm{N}_{00}\mathrm{c}`\beta . \gamma \cap \delta = \Lambda$

$*106\cdot4\cdot41\cdot411$. $\vdash : \mu = \mathrm{N}_0\mathrm{c}`\alpha . \supset . \mu_{(00)} = \mathrm{N}_{00}\mathrm{c}`\alpha . \mu^{(11)} = \mathrm{N}^{11}\mathrm{c}`\alpha . \mu_{(11)} = \mathrm{N}_{11}\mathrm{c}`\alpha$

$*106\cdot53$. $\vdash . \operatorname{Nc}(\alpha)`t_{00}`\alpha = \Lambda$

whence it follows that

$*106\cdot54$. $\vdash . \mathrm{N}_0\mathrm{c}`t_{00}`\alpha \sim\in \mathrm{N}_{00}\mathrm{C}$

The propositions of this number, except $*106{\cdot}21$, are never referred to again (except in $*154{\cdot}25{\cdot}251{\cdot}262$, which are themselves never used again), but they have a somewhat greater importance than the propositions of $*105$, owing to the fact that the arithmetical operations are defined by means of classes of relations, *i.e.* the sum of two cardinals (for instance) is defined as the cardinal number of a certain class of relations (cf. $*110$).

$*106{\cdot}01$. $\mathrm{N}_{00}\mathrm{c}\text{‘}\alpha = \mathrm{Nc}\text{‘}\alpha \cap t\text{‘}t_{00}\text{‘}\alpha$ Df

$*106{\cdot}011$. $\mathrm{N}^{11}\mathrm{c}\text{‘}\alpha = \mathrm{Nc}\text{‘}\alpha \cap t\text{‘}t^{11}\text{‘}\alpha$ Df

Other propositions of the same kind as the above may be proved by observing that, if m and n are indices for which $t^m{}^\backprime\alpha$ and $t^n{}^\backprime\alpha$ have been defined, we have

$$\gamma \subset t^n{}^\backprime\alpha . \beta \epsilon \mathrm{N}^m\mathrm{c}^\backprime\alpha . \supset . \downarrow \beta^{\backprime\backprime}\gamma \epsilon \mathrm{N}^{mn}\mathrm{c}^\backprime\alpha,$$

of which the proof is direct and simple. Hence, since we always have $\exists ! \mathrm{N}^m\mathrm{c}^\backprime\alpha$, we also always have

$$\exists ! \mathrm{N}^{mn}\mathrm{c}^\backprime\alpha,$$

whence $\qquad \mathrm{N}^{mn}\mathrm{C} \subset \mathrm{N}_0\mathrm{C} . \mathrm{N}^{mn}\mathrm{C} \epsilon \mathrm{Cls\,ex}^2\,\mathrm{excl}.$

We have in like manner

$$\exists ! \mathrm{N}_0{}^m\mathrm{c}^\backprime\alpha . \exists ! {}^m\mathrm{N}_0\mathrm{c}^\backprime\alpha.$$

But we do not always have

$$\exists ! \mathrm{N}_{mn}\mathrm{c}^\backprime\alpha \text{ or } \exists ! \mathrm{N}_n{}^m\mathrm{c}^\backprime\alpha \text{ or } \exists ! {}^m\mathrm{N}_n\mathrm{c}^\backprime\alpha.$$

SECTION B

ADDITION, MULTIPLICATION AND EXPONENTIATION

Summary of Section B.

In the present section, we have to consider the arithmetical operations as applied to cardinals, as well as the relation of greater and less between cardinals. Thus the topics to be dealt with in this section are the first that can properly be said to belong to Arithmetic.

The treatment of addition, multiplication and exponentiation to be given in what follows is guided by the desire to secure the greatest possible generality. In the first place, everything to be said generally about the arithmetical operations must apply equally to finite and infinite classes or cardinals. In the second place, we desire such definitions as shall allow the number of summands in a sum or of factors in a product to be infinite. In the third place, we wish to be able to add or multiply two numbers which are not necessarily of the same type. In the fourth place, we wish our definitions to be such that the sum of the cardinal numbers of two or more classes shall depend only upon the cardinal numbers of those classes, and shall be the same when the classes overlap as when they are mutually exclusive; with similar conditions for the product. The desire to obtain definitions fulfilling all these conditions leads to somewhat more complicated definitions than would otherwise be required; but in the outcome, the result is simpler than if we started with simpler definitions, since we avoid vexatious exceptions.

The above observations will become clearer through their applications. Let us begin with the case of arithmetical addition of two classes.

If α and β are mutually exclusive classes, the sum of their cardinal numbers will be the cardinal number of $\alpha \cup \beta$. But in order that α and β may be mutually exclusive, they must have no common members, and this is only significant when they are of the same type. Hence, given two perfectly general classes α and β, we require to find two classes which are mutually exclusive and are respectively similar to α and β; if these two classes are called α' and β', then $\mathrm{Nc}`(\alpha' \cup \beta')$ will be the sum of the cardinal numbers of α and β. We note that $\Lambda \cap \alpha$ and $\Lambda \cap \beta$ indicate respectively the Λ's of the same types as α and β, and accordingly we take as α' and β' the two classes

$$\downarrow (\Lambda \cap \beta)``\iota``\alpha \text{ and } (\Lambda \cap \alpha) \downarrow ``\iota``\beta;$$

these two classes are always of the same type, always mutually exclusive, and always similar to α and β respectively. Hence we define

$$\alpha + \beta = \downarrow (\Lambda \cap \beta)``\iota``\alpha \cup (\Lambda \cap \alpha) \downarrow ``\iota``\beta \quad \text{Df.}$$

The sum of the cardinal numbers of α and β will then be the cardinal number of $\alpha+\beta$; hence we may call $\alpha+\beta$ the *arithmetical* class-sum of two classes, in contradistinction to $\alpha \cup \beta$, which is the *logical* sum. It will be noted that $\alpha+\beta$, unlike $\alpha \cup \beta$, does not require that α and β should be of the same type. Also $\alpha+\alpha$ is not identical with α, but when $\alpha=\Lambda$, $\alpha+\alpha$ is also Λ, though in a different type. Thus the law of tautology does not hold of the arithmetical class-sum of two classes.

If μ and ν are two cardinals of assigned types, we denote their arithmetical sum by $\mu +_c \nu$. (As many kinds of arithmetical addition occur in our work, and as it is essential to our purpose to distinguish them, we effect the distinction by suffixes to the sign of addition. It is, of course, only in dealing with principles that these different symbols are needed: we do not wish to suggest that they should be adopted in ordinary mathematics.) Now if $\mu +_c \nu$ is to have the properties which we commonly associate with the sum of two cardinals, it must be typically ambiguous, and must be the cardinal number of any class which can be divided into two mutually exclusive parts having μ terms and ν terms respectively. Hence we are led to the following definition:

$$\mu +_c \nu = \hat{\xi}\{(\exists \alpha, \beta) . \mu = \mathrm{N_0c}`\alpha . \nu = \mathrm{N_0c}`\beta . \xi \,\mathrm{sm}\, (\alpha+\beta)\} \quad \mathrm{Df.}$$

In this definition, various points should be noted. In the first place, it does not require that μ and ν should be of the same type; $\mu +_c \nu$ is *significant* whenever μ and ν are classes of classes. Thus it is not necessary for significance that μ and ν should be cardinals, though if they are not both cardinals, $\mu +_c \nu = \Lambda$. If they are both cardinals, we find

$$\mu +_c \nu = \hat{\xi}\{(\exists \alpha, \beta) . \alpha \epsilon \mu . \beta \epsilon \nu . \xi \,\mathrm{sm}\, (\alpha+\beta)\}.$$

Thus in this case $\quad \alpha \epsilon \mu . \beta \epsilon \nu . \supset . \alpha+\beta \epsilon \mu +_c \nu.$

Hence if neither μ nor ν is null, and if α has μ terms and β has ν terms, $\alpha+\beta$ is a member of $\mu +_c \nu$. It easily follows that

$$\vdash : \mu = \mathrm{N_0c}`\alpha . \nu = \mathrm{N_0c}`\beta . \supset . \mu +_c \nu = \mathrm{Nc}`(\alpha+\beta).$$

Hence when μ and ν are homogeneous cardinals (*i.e.* when they are cardinals other than Λ), their sum is the number of the arithmetical class-sum of any two classes having μ terms and ν terms respectively.

A few words are necessary to explain why, in the definition, we put $\mu = \mathrm{N_0c}`\alpha . \nu = \mathrm{N_0c}`\beta$ rather than $\mu = \mathrm{Nc}`\alpha . \nu = \mathrm{Nc}`\beta$. The reason is this. Suppose either μ or ν, say μ, is Λ. Then, by $*102{\cdot}73$, $\mu = \mathrm{Nc}(\zeta)`t`\zeta$, if ζ is of the appropriate type. Hence if we had put

$$\mu +_c \nu = \hat{\xi}\{(\exists \alpha, \beta) . \mu = \mathrm{Nc}`\alpha . \nu = \mathrm{Nc}`\beta . \xi \,\mathrm{sm}\, (\alpha+\beta)\} \quad \mathrm{Df,}$$

where the ambiguities of type involved in $\mathrm{Nc}`\alpha$ and $\mathrm{Nc}`\beta$ may be determined as we please, we should have

$$\nu = \mathrm{Nc}`\beta . \supset . t`\zeta + \beta \epsilon \mu +_c \nu,$$

i.e. $\quad \nu = \mathrm{Nc}`\beta . \supset . t`\zeta + \beta \epsilon \Lambda +_c \nu.$

We should also have $t`t`\zeta + \beta \epsilon \Lambda +_c \nu$ and so on. Thus $\Lambda +_c \nu$ would not have a definite value, *i.e.* it would not merely have typical ambiguity, which it ought to have, but it would not have a definite value even when its type was assigned. Thus such a definition would be unsuitable. For the above reasons, we put $\mu = \mathrm{N_0c}`\alpha \,.\, \nu = \mathrm{N_0c}`\beta$ in the definition, and obtain the typical ambiguity which we desire by means of the typical ambiguity of the "sm" in "$\xi \,\mathrm{sm}\,(\alpha + \beta)$." It is always essential to right symbolism that the values of typically ambiguous symbols should be unique as soon as their type is assigned. The scope of these definitions and of the corresponding definitions for multiplication and exponentiation (*113·04·05 . *116·03·04) is extended by convention II T of the prefatory statement.

The above definition of $\mu +_c \nu$ is designed for the case in which μ and ν are typically definite. But we must be able to speak of "$\mathrm{Nc}`\gamma +_c \mathrm{Nc}`\delta$," and this must be a definite cardinal, namely $\mathrm{Nc}`(\gamma + \delta)$. If we simply write $\mathrm{Nc}`\gamma$, $\mathrm{Nc}`\delta$ in place of μ, ν in the definition of $\mu +_c \nu$, we find

$$\mathrm{Nc}`\gamma +_c \mathrm{Nc}`\delta = \hat{\xi}\{(\exists \alpha, \beta) \,.\, \mathrm{Nc}`\gamma = \mathrm{N_0c}`\alpha \,.\, \mathrm{Nc}`\delta = \mathrm{N_0c}`\beta \,.\, \xi \,\mathrm{sm}\,(\alpha + \beta)\}.$$

But this will not always have a definite value when the type of $\mathrm{Nc}`\gamma +_c \mathrm{Nc}`\delta$ is assigned. To take a simple case, write $t`\zeta$ for $\gamma$ and $\iota`y$ for δ. Then

$$\mathrm{Nc}`t`\zeta +_c \mathrm{Nc}`\iota`y = \hat{\xi}\{(\exists \alpha, \beta) \,.\, \mathrm{Nc}`t`\zeta = \mathrm{N_0c}`\alpha \,.\, \mathrm{Nc}`\iota`y = \mathrm{N_0c}`\beta \,.\, \xi \,\mathrm{sm}\,(\alpha + \beta)\},$$

whence we easily obtain

$$\mathrm{Nc}`t`\zeta +_c \mathrm{Nc}`\iota`y = \hat{\xi}\{(\exists \alpha) \,.\, \mathrm{Nc}`t`\zeta = \mathrm{N_0c}`\alpha \,.\, \xi \,\mathrm{sm}\,(\alpha + \iota`y)\}.$$

If we determine the ambiguity of $\mathrm{Nc}`t`\zeta$ to be $\mathrm{N_1c}`t`\zeta$, we find

$$\mathrm{Nc}`t`\zeta +_c \mathrm{Nc}`\iota`y = \Lambda$$

in all types; but if we determine the ambiguity to be $\mathrm{N_0c}`t`\zeta$, we have

$$\mathrm{Nc}`t`\zeta +_c \mathrm{Nc}`\iota`y = \mathrm{Nc}`(t`\zeta + \iota`y),$$

and this exists in the type of $t`\zeta + \iota`y$, if not in lower types. Hence the value of $\mathrm{Nc}`t`\zeta +_c \mathrm{Nc}`\iota`y$ depends upon the determination of the ambiguity of $\mathrm{Nc}`t`\zeta$. It is obvious that we want our definition to yield

$$\mathrm{Nc}`\gamma +_c \mathrm{Nc}`\delta = \mathrm{Nc}`(\gamma + \delta)$$

in all types; but in order to insure that this shall hold even when, for some values of ζ, $\mathrm{Nc}\,(\zeta)`\gamma = \Lambda$, we must introduce two new definitions, namely

$$\mathrm{Nc}`\alpha +_c \mu = \mathrm{N_0c}`\alpha +_c \mu \quad \mathrm{Df},$$

$$\mu +_c \mathrm{Nc}`\alpha = \mu +_c \mathrm{N_0c}`\alpha \quad \mathrm{Df},$$

whence $\quad \vdash : \mathrm{Nc}`\alpha +_c \mathrm{Nc}`\beta = \mathrm{N_0c}`\alpha +_c \mathrm{N_0c}`\beta = \mathrm{Nc}`(\alpha + \beta).$

This definition is to be applied when "$\mathrm{Nc}`\gamma$" and "$\mathrm{Nc}`\delta$" occur without any determination of type. On the other hand, if we have $\mathrm{Nc}\,(\zeta)`\gamma$ and $\mathrm{Nc}\,(\eta)`\delta$, we apply the definition of $\mu +_c \nu$. We shall find that whenever $\mathrm{Nc}\,(\zeta)`\gamma$ and $\mathrm{Nc}\,(\eta)`\delta$ both exist,

$$\mathrm{Nc}\,(\zeta)`\gamma +_c \mathrm{Nc}\,(\eta)`\delta = \mathrm{N_0c}`\gamma +_c \mathrm{N_0c}`\delta.$$

Thus the above definition is only required in order to exclude values of ζ or η for which either $\mathrm{Nc}\,(\zeta)`\gamma$ or $\mathrm{Nc}\,(\eta)`\delta$ is Λ.

The commutative and associative laws of arithmetical addition are easily deduced from the definition of $\alpha + \beta$. We shall have

$$\vdash . \alpha + \beta = \mathrm{Cnv}``(\beta + \alpha),$$

whence $$\vdash . \mathrm{Nc}`\alpha +_c \mathrm{Nc}`\beta = \mathrm{Nc}`\beta +_c \mathrm{Nc}`\alpha,$$

because each $= \mathrm{Nc}`(\alpha + \beta)$. A similar though slightly longer proof shows that

$$\vdash . (\alpha + \beta) + \gamma \,\mathrm{sm}\, \alpha + (\beta + \gamma),$$

whence $$\vdash . (\mathrm{Nc}`\alpha +_c \mathrm{Nc}`\beta) +_c \mathrm{Nc}`\gamma = \mathrm{Nc}`\alpha +_c (\mathrm{Nc}`\beta +_c \mathrm{Nc}`\gamma).$$

The above definition of $\alpha + \beta$ enables us to proceed to the sum of any finite number of classes, and allows any one class to recur in the summation. But it does not enable us to define the sum of an infinite number of classes. For this we need a new definition. Since an infinite number of classes cannot be given by enumeration, but only by intension, we shall have to take a class of classes κ, and define the arithmetical sum of the members of κ. Thus now the classes which are the summands must all be of the same type (since they are all members of κ), and no one class can occur more than once, since each member of κ only counts once. (In order to deal with repetition, we must advance to multiplication, which will be explained shortly.) Thus in removing the limitation to a finite number of summands, we introduce certain other limitations. This is the reason which makes it worth while to introduce the above definition of $\alpha + \beta$ in addition to the definition now to be given.

If κ is a class of classes, the sum of the cardinal numbers of the members of κ will evidently be obtained by constructing a class of mutually exclusive classes whose members have a one-one relation to the members of corresponding members of κ. Suppose α, β are two different members of κ, and suppose x is a member both of α and of β. Then we wish to count x twice over, once as a member of α and once as a member of β. The simplest way to do this is to form the ordinal couples $x \downarrow \alpha$ and $x \downarrow \beta$, which are not identical except when α and β are identical. Thus if we take all such ordinal couples, *i.e.* if we take the class

$$\hat{R}\{(\exists x) . x \epsilon \alpha . R = x \downarrow \alpha\},$$

for every α which is a member of κ, we get a class of mutually exclusive classes, namely the classes of the form $\downarrow \alpha``\alpha$, where $\alpha \epsilon \kappa$, and each of these is similar to the corresponding member of κ. Hence the logical sum of this class of classes, *i.e.*

$$\hat{R}\{(\exists \alpha, x) . \alpha \epsilon \kappa . x \epsilon \alpha . R = x \downarrow \alpha\},$$

has the required number of terms. Now, by $*85{\cdot}601$,

$$\downarrow \alpha``\alpha = \epsilon \,\rotatebox[origin=c]{180}{$\uparrow$}`\alpha.$$

Hence the class whose logical sum we are taking is $\epsilon \,\rotatebox[origin=c]{180}{$\uparrow$}``\kappa$. Hence we put

$$\Sigma`\kappa = s`\epsilon \,\rotatebox[origin=c]{180}{$\uparrow$}``\kappa \quad \mathrm{Df.}$$

$\Sigma`\kappa$ may be called the *arithmetical* sum of $\kappa$, in contradistinction to $s`\kappa$, which is the logical sum. Thus $\Sigma`\kappa$ bears to $s`\kappa$ a relation analogous to that which $\alpha + \beta$ bears to $\alpha \cup \beta$.

We put further $\quad \Sigma\text{Nc}‘\kappa = \text{Nc}‘s‘\epsilon\downarrow``\kappa \quad$ Df.

Thus $\Sigma\text{Nc}‘\kappa$ is the sum of the numbers of members of κ.

It is to be observed that $\Sigma\text{Nc}‘\kappa$ is not in general a function of $\text{Nc}``\kappa$. For, if two members of $\kappa$ have the same cardinal number, this will only count once in $\text{Nc}``\kappa$, whereas it counts twice in $\Sigma\text{Nc}‘\kappa$.

We shall find that, provided $\alpha \neq \beta$,

$$\Sigma\text{Nc}‘(\iota‘\alpha \cup \iota‘\beta) = \text{Nc}‘\alpha +_0 \text{Nc}‘\beta.$$

Thus where a finite number of summands are concerned, the two definitions of addition agree, except that the first allows one class to count several times over, while the second does not.

In dealing with multiplication, our procedure is closely analogous to the procedure for addition. We first define the *arithmetical class-product* of two classes α and β, which is a certain class whose cardinal number is the product of the cardinal numbers of α and β. We write $\beta \times \alpha$ for the arithmetical class-product of β and α, and define it as the class of all ordinal couples of which the referent is a member of α and the relatum a member of β, *i.e.* as

$$\hat{R}\{(\exists x, y) \,.\, x \in \alpha \,.\, y \in \beta \,.\, R = x \downarrow y\}.$$

By *40·7, this class is $s‘\alpha \underset{,,}{\downarrow} ``\beta$. Hence we put

$$\beta \times \alpha = s‘\alpha \underset{,,}{\downarrow} ``\beta \quad \text{Df.}$$

The class $\alpha \underset{,,}{\downarrow} ``\beta$ is similar to $\beta$, and each member of it is similar to $\alpha$; hence if $\text{N}_0\text{c}‘\alpha = \mu$ and $\text{N}_0\text{c}‘\beta = \nu$, $s‘\alpha \underset{,,}{\downarrow} ``\beta$ consists of ν classes having μ members each. The class $\alpha \underset{,,}{\downarrow} ``\beta$ is important also in connection with exponentiation. The product of two cardinals is defined as follows:

$$\mu \times_0 \nu = \hat{\xi}\{(\exists \alpha, \beta) \,.\, \mu = \text{N}_0\text{c}‘\alpha \,.\, \nu = \text{N}_0\text{c}‘\beta \,.\, \xi \,\text{sm}\, (\alpha \times \beta)\} \quad \text{Df.}$$

In regard to types, this definition calls for analogous remarks to those which were made on $\mu +_0 \nu$. Also, as before, we need definitions of $\mu \times_0 \text{Nc}‘\alpha$ and $\text{Nc}‘\alpha \times_0 \mu$, whence we obtain

$$\text{Nc}‘\alpha \times_0 \text{Nc}‘\beta = \text{N}_0\text{c}‘\alpha \times_0 \text{N}_0\text{c}‘\beta \quad \text{Df.}$$

By means of these definitions, we can define the product of any finite number of cardinals; but in order to define products which have an infinite number of factors, we need a new definition.

If κ is a class of classes, we take $\epsilon_\Delta‘\kappa$ as its arithmetical product. In simple cases, it is easy to see the justification of this decision. *E.g.* let κ consist of the three classes $\alpha_1, \alpha_2, \alpha_3$, and let the members of α_1 be x_1, x_2; those of α_2, y_1, y_2; those of α_3, z_1, z_2. Then the members of $\epsilon_\Delta‘\kappa$ are

$$x_1 \downarrow \alpha_1 \cup y_1 \downarrow \alpha_2 \cup z_1 \downarrow \alpha_3,$$
$$x_2 \downarrow \alpha_1 \cup y_1 \downarrow \alpha_2 \cup z_1 \downarrow \alpha_3,$$
$$x_1 \downarrow \alpha_1 \cup y_2 \downarrow \alpha_2 \cup z_1 \downarrow \alpha_3,$$
$$x_2 \downarrow \alpha_1 \cup y_2 \downarrow \alpha_2 \cup z_1 \downarrow \alpha_3,$$

with four more obtained by substituting z_2 for z_1 in the above. Thus $\mathrm{Nc}`\epsilon_\Delta`\kappa = 8 = \mathrm{Nc}`\alpha_1 \times_0 \mathrm{Nc}`\alpha_2 \times_0 \mathrm{Nc}`\alpha_3$. In general, however, the existence of $\epsilon_\Delta`\kappa$ is doubtful, owing to the doubt as to the validity of the multiplicative axiom. (We shall return to this point shortly.) Hence there is no proof that the product of an infinite number of factors cannot be zero unless one of the factors is zero.

When κ is a class of mutually exclusive classes, $\epsilon_\Delta`\kappa$ is similar to $\mathrm{D}``\epsilon_\Delta`\kappa$. On account of its lower type, $\mathrm{D}``\epsilon_\Delta`\kappa$ is often more convenient than $\epsilon_\Delta`\kappa$. Hence we put

$$\mathrm{Prod}`\kappa = \mathrm{D}``\epsilon_\Delta`\kappa \quad \mathrm{Df},$$

or (what comes to the same thing)

$$\mathrm{Prod} = \mathrm{D}_\epsilon | \epsilon_\Delta \quad \mathrm{Df}.$$

For the product of the cardinal numbers of the members of κ, we put

$$\Pi\mathrm{Nc}`\kappa = \mathrm{Nc}`\epsilon_\Delta`\kappa \quad \mathrm{Df}.$$

As in the case of $\Sigma\mathrm{Nc}`\kappa$, $\Pi\mathrm{Nc}`\kappa$ is not in general a function of $\mathrm{Nc}``\kappa$. We shall have

$$\vdash : \alpha \neq \beta \,.\supset .\, \Pi\mathrm{Nc}`(\iota`\alpha \cup \iota`\beta) = \mathrm{Nc}`\alpha \times_c \mathrm{Nc}`\beta.$$

Thus for products of a finite number of different factors, the two definitions of multiplication agree.

It remains to define exponentiation. Since this is not a commutative operation, it essentially involves an order as between the base and the exponent; hence we do not obtain a definition of the exponentiation of a class κ, analogous to $\Sigma\mathrm{Nc}`\kappa$ or $\Pi\mathrm{Nc}`\kappa$, but only a definition of μ^ν, which may be extended to any finite number of exponentiations. We put

$$\alpha \exp \beta = \mathrm{Prod}`\alpha \underset{,,}{\downarrow} ``\beta \quad \mathrm{Df},$$

where $\alpha \underset{,,}{\downarrow} ``\beta$ has the meaning explained above, resulting from $*38{\cdot}03$. It will be observed that, if $\mathrm{N_0c}`\alpha = \mu$ and $\mathrm{N_0c}`\beta = \nu$, $\alpha \underset{,,}{\downarrow} ``\beta$ is a class of ν mutually exclusive classes each of which has μ terms; hence $\alpha \exp \beta$ may suitably be used to define μ^ν. Hence we put

$$\mu^\nu = \hat{\xi}\{(\exists \alpha, \beta) \,.\, \mu = \mathrm{N_0c}`\alpha \,.\, \nu = \mathrm{N_0c}`\beta \,.\, \xi \,\mathrm{sm}\, (\alpha \exp \beta)\} \quad \mathrm{Df},$$

and for the same reasons as before, we put

$$(\mathrm{Nc}`\alpha)^\nu = (\mathrm{N_0c}`\alpha)^\nu \quad \mathrm{Df} \text{ and } \mu^{\mathrm{Nc}`\beta} = \mu^{\mathrm{N_0c}`\beta} \quad \mathrm{Df}.$$

The above definition of exponentiation gives the same value of μ^ν as results from Cantor's definition by means of "Belegungen." The class of Cantor's "Belegungen" is

$$\hat{R}\{R \epsilon 1 \rightarrow \mathrm{Cls} \,.\, \mathrm{D}`R \subset \alpha \,.\, \mathrm{Cl}`R = \beta\},$$

i.e.

$$(\alpha \uparrow \beta)_\Delta`\beta,$$

and it is easily proved that this is similar to $\alpha \exp \beta$.

The usual formal properties of exponentiation result without much difficulty from the above definitions.

The above definition of exponentiation is so framed as to make propositions on exponentiation independent of the multiplicative axiom, except when exponentiation is to be connected with multiplication, *i.e.* when it is to be shown that the product of ν factors, each of which is μ, is μ^ν. This proposition cannot be proved generally without the multiplicative axiom. Similarly, in the theory of multiplication, the proposition that the sum of ν μ's is $\mu \times_c \nu$ requires the multiplicative axiom (as does also the proposition that a product is zero when and only when one of its factors is zero). Otherwise, the theory of multiplication proceeds without the need for employing the multiplicative axiom.

To take first the connection of addition and multiplication: this connection, in the form in which we naturally suppose it to hold, is affirmed in the proposition:

$$\mu, \nu \in \mathrm{NC} \,.\, \kappa \in \nu \cap \mathrm{Cls\,excl}`\mu \,.\supset .\, s`\kappa \in \mu \times_c \nu \qquad \text{(A)}$$

or

$$\mu, \nu \in \mathrm{NC} \,.\, \kappa \in \nu \cap \mathrm{Cl}`\mu \,.\supset .\, \Sigma`\kappa \in \mu \times_c \nu.$$

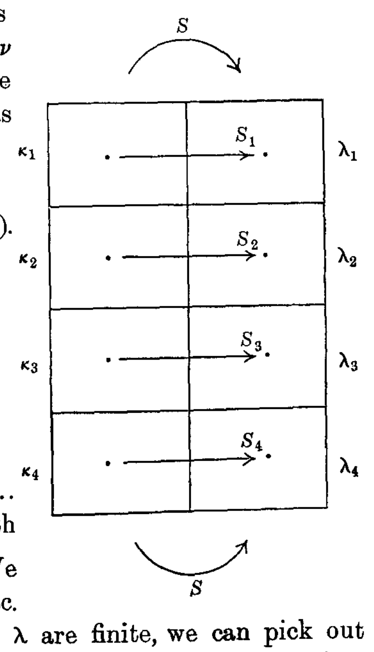
We will take the first of these as being simpler. It affirms that the sum of ν μ's is $\mu \times_c \nu$. This can be proved when ν is finite, whether μ is finite or not; but when ν is infinite, it cannot be proved without the multiplicative axiom. This may be seen as follows. We know that

$$\vdash : \mu, \nu \in \mathrm{NC} \,.\, \alpha \in \mu \,.\, \beta \in \nu \,.\supset .$$
$$\alpha \underset{,,}{\downarrow} \text{``}\beta \in \nu \cap \mathrm{Cls\,excl}`\mu \,.\, s`\alpha \underset{,,}{\downarrow} \text{``}\beta \in \mu \times_c \nu \qquad \text{(B)}.$$

Thus (A) above will result if we can prove

$$\kappa, \lambda \in \nu \cap \mathrm{Cls\,excl}`\mu \,.\supset .\, s`\kappa \,\mathrm{sm}\, s`\lambda,$$

since we shall put $\alpha \underset{,,}{\downarrow} \text{``}\beta$ for λ and use (B).



Since $\kappa, \lambda \in \nu$, we have $\kappa \,\mathrm{sm}\, \lambda$. Assume

$$S \in 1 \rightarrow 1 \,.\, \mathrm{D}`S = \kappa \,.\, \mathrm{Cl}`S = \lambda.$$

Let $\kappa_1, \kappa_2, \ldots$ be members of κ, and let $\lambda_1, \lambda_2, \ldots$ be the members of λ which are correlated with $\kappa_1, \kappa_2, \ldots$ by S, *i.e.* $\lambda_1 = \breve{S}`\kappa_1 \,.\, \lambda_2 = \breve{S}`\kappa_2 \,.$ etc. We have, since $\kappa, \lambda \in \mathrm{Cl}`\mu$, $\kappa_1 \,\mathrm{sm}\, \lambda_1 \,.\, \kappa_2 \,\mathrm{sm}\, \lambda_2 \,.$ etc. Thus $\alpha S \beta \,.\supset_{\alpha,\beta} .\, \alpha \,\mathrm{sm}\, \beta$, *i.e.* $S \subset \mathrm{sm}$. If κ and λ are finite, we can pick out arbitrarily a correlation S_1 for κ_1 and λ_1, another S_2 for κ_2 and λ_2, and so on; then $S_1 \cup S_2 \cup \ldots$ correlates $s`\kappa$ and $s`\lambda$, and therefore $s`\kappa \,\mathrm{sm}\, s`\lambda$. But when κ and λ are infinite, this method is impracticable. In this case, we proceed as follows.

By *73·01, $\quad \alpha \,\overline{\mathrm{sm}}\, \beta = (1 \rightarrow 1) \cap \overleftarrow{\mathrm{D}}`\alpha \cap \overleftarrow{\mathrm{Cl}}`\beta \quad$ Df.

Thus "$\alpha \,\overline{\mathrm{sm}}\, \alpha$" will stand for all the permutations of a class into itself; "$\alpha \,\overline{\mathrm{sm}}\, \beta$" stands for all the permutations of α into β, *i.e.* all the $1 \rightarrow 1$'s whose

domain is α and whose converse domain is β. It is obvious that

$$\vdash : \exists ! \, \alpha \, \overline{\mathrm{sm}} \, \beta \cap \gamma \, \overline{\mathrm{sm}} \, \delta \, . \supset . \, \alpha = \gamma \, . \, \beta = \delta .$$

In the case of the κ and λ above, we know that $\alpha \, \mathrm{sm} \, \beta$ when $\alpha S \beta$; thus

$$\alpha \in \kappa \, . \supset_\alpha . \, \exists ! \, \alpha \, \overline{\mathrm{sm}} \, (\breve{S}\text{‘}\alpha)$$

or

$$\beta \in \lambda \, . \supset_\beta . \, \exists ! \, (S\text{‘}\beta) \, \overline{\mathrm{sm}} \, \beta .$$

Put $$\mathrm{Crp} \, (S)\text{‘}\beta = (S\text{‘}\beta) \, \overline{\mathrm{sm}} \, \beta \quad \mathrm{Df},$$

where "Crp" stands for "correspondence." Thus $\mathrm{Crp}\,(S)\text{‘}\beta$ is the class of all correspondences of $S\text{‘}\beta$ and β; $\mathrm{Crp}\,(S)\text{‘‘}\lambda$ is the class of all such classes of correspondences. If we extract one member out of each of these classes of correspondences, we get a class of relations whose sum is a correlator of $s\text{‘}\kappa$ and $s\text{‘}\lambda$; *i.e.*

$$\varpi \in \mathrm{D}\text{‘‘}\epsilon_\Delta\text{‘}\mathrm{Crp}\,(S)\text{‘‘}\lambda \, . \supset . \, \dot{s}\text{‘}\varpi \in (s\text{‘}\kappa) \, \overline{\mathrm{sm}} \, (s\text{‘}\lambda).$$

Thus the desired result follows whenever

$$\exists ! \, \epsilon_\Delta\text{‘}\mathrm{Crp} \, (S)\text{‘‘}\lambda.$$

Now we have $S \in 1 \to 1 \, . \, S \subseteq \mathrm{sm} \, . \supset . \, \mathrm{Crp}\,(S)\text{‘‘}\lambda \in \mathrm{Cls\,ex^2\,excl}.$

Consequently

$$\mathrm{Mult\,ax} \, . \supset : S \in 1 \to 1 \, . \, S \subseteq \mathrm{sm} \, . \, \mathrm{D}\text{‘}S = \kappa \, . \, \mathrm{Ꮧ}\text{‘}S = \lambda \, . \, \kappa, \lambda \in \mathrm{Cls^2\,excl} \, . \supset . \, s\text{‘}\kappa \, \mathrm{sm} \, s\text{‘}\lambda,$$

whence, by what was said previously,

$$\mathrm{Mult\,ax} \, . \supset : \kappa \in \nu \cap \mathrm{Cls\,excl}\text{‘}\mu \, . \supset . \, s\text{‘}\kappa \in \mu \times_0 \nu \, . \, \Sigma\mathrm{Nc}\text{‘}\kappa = \mu \times_0 \nu.$$

The consideration of $\epsilon_\Delta\text{‘}\mathrm{Crp}\,(S)\text{‘‘}\lambda$ leads similarly to the proposition

$$\vdash :. \, \mathrm{Mult\,ax} \, . \supset : \mu, \nu \in \mathrm{NC} \, . \, \kappa \in \nu \cap \mathrm{Cl}\text{‘}\mu \, . \supset . \, \epsilon_\Delta\text{‘}\kappa \in \mu^\nu \, . \, \Pi\mathrm{Nc}\text{‘}\kappa = \mu^\nu.$$

The proof is closely analogous to that for the connection of addition and multiplication.

It will be seen that, in the above use of the multiplicative axiom, we have two classes of classes κ and λ concerning which we assume

$$(\exists S) \, . \, S \in 1 \to 1 \, . \, S \subseteq \mathrm{sm} \, . \, \mathrm{D}\text{‘}S = \kappa \, . \, \mathrm{Ꮧ}\text{‘}S = \lambda,$$

i.e. we assume that κ and λ are similar classes of similar classes. A slightly modified hypothesis concerning κ and λ will enable us to obtain many results, without the multiplicative axiom, which otherwise might be expected to require this axiom. This is effected as follows.

Put $$\kappa \, \mathrm{sm\,sm} \, \lambda \, . \equiv . \, (\exists T) \, . \, T \in 1 \to 1 \, . \, \mathrm{Ꮧ}\text{‘}T = s\text{‘}\lambda \, . \, \kappa = T_\epsilon\text{‘‘}\lambda,$$

where "sm sm" is a single symbol representing a relation.

When this relation holds between κ and λ, we shall say that κ and λ have "double similarity." In this case, T correlates $s\text{‘}\kappa$ and $s\text{‘}\lambda$, while T_ϵ correlates κ and λ, so that if β is a member of λ, $T_\epsilon\text{‘}\beta$, *i.e.* $T\text{‘‘}\beta$, is its correlate in κ. We shall then have

$$\vdash : \kappa \, \mathrm{sm\,sm} \, \lambda \, . \supset . \, s\text{‘}\kappa \, \mathrm{sm} \, s\text{‘}\lambda,$$

$$\vdash : \kappa \, \mathrm{sm\,sm} \, \lambda \, . \supset . \, \Sigma\mathrm{Nc}\text{‘}\kappa = \Sigma\mathrm{Nc}\text{‘}\lambda,$$

$$\vdash : \kappa \, \mathrm{sm\,sm} \, \lambda \, . \supset . \, \Pi\mathrm{Nc}\text{‘}\kappa = \Pi\mathrm{Nc}\text{‘}\lambda.$$

Also we have

$$\vdash : \kappa \operatorname{sm} \operatorname{sm} \lambda . \supset . (\exists S) . S \in 1 \to 1 . S \mathrel{\subset} \operatorname{sm} . \mathrm{D}`S = \kappa . \mathrm{G}`S = \lambda.$$

Conversely,

$$\vdash : \kappa, \lambda \in \mathrm{Cls}^2 \operatorname{excl} . S \in 1 \to 1 . S \mathrel{\subset} \operatorname{sm} . \mathrm{D}`S = \kappa . \mathrm{G}`S = \lambda .$$
$$\varpi \in \mathrm{D}``\epsilon_\Delta`\mathrm{Crp}(S)``\lambda . T = \dot{s}`\varpi . \supset . T \in 1 \to 1 . \mathrm{G}`T = s`\lambda . \kappa = T_\epsilon``\lambda,$$

whence

$$\vdash :: \text{Mult ax} . \supset :. \kappa, \lambda \in \mathrm{Cls}^2 \operatorname{excl} : (\exists S) . S \in 1 \to 1 . S \mathrel{\subset} \operatorname{sm} . \mathrm{D}`S = \kappa . \mathrm{G}`S = \lambda : \supset . \kappa \operatorname{sm} \operatorname{sm} \lambda.$$

Hence the multiplicative axiom is only required in order to pass from

$$(\exists S) . S \in 1 \to 1 . S \mathrel{\subset} \operatorname{sm} . \mathrm{D}`S = \kappa . \mathrm{G}`S = \lambda$$

to $\kappa \operatorname{sm} \operatorname{sm} \lambda$. It is this fact, and the consequent possibility of diminishing the use of the multiplicative axiom, which has led us to the employment of "sm sm" in the present section.

We treat also, in this section, the relation of greater and less between cardinals. We say that $\mathrm{Nc}`\alpha > \mathrm{Nc}`\beta$ when there is a part of α which is similar to β, but no part of β is similar to α. The principal proposition in this subject is the Schröder-Bernstein theorem, *i.e.*

$$\vdash : \mu \geqslant \nu . \nu \geqslant \mu . \supset . \mu = \nu.$$

This is an immediate consequence of *73·88. It cannot be shown, without assuming the multiplicative axiom, that of any two cardinals one must be the greater, *i.e.*

$$\mu, \nu \in \mathrm{NC} . \mu \neq \nu . \supset : \mu > \nu . \vee . \nu > \mu.$$

If we assume the multiplicative axiom, this results from Zermelo's proof that on that assumption, every class can be well-ordered, together with Cantor's proof that of any two well-ordered series which are not similar, one must be similar to a part of the other. But these propositions cannot be proved till a much later stage (*258).

$*110$. THE ARITHMETICAL SUM OF TWO CLASSES AND OF TWO CARDINALS

Summary of $*110$.

In this number, we start from the definition:

$*110\cdot01$. $\alpha + \beta = \downarrow(\Lambda \cap \beta)\text{“}\iota\text{“}\alpha \cup (\Lambda \cap \alpha)\downarrow\text{“}\iota\text{“}\beta$ Df

$\alpha + \beta$ is called the "arithmetical class-sum" of α and β. The definition is framed so as to give two mutually exclusive classes respectively similar to α and β, so that the number of terms in the logical sum of these two classes is the arithmetical sum of the numbers of terms in α and β respectively. $\alpha + \beta$ is significant whenever α and β are classes, whatever their types may be.

By means of $\alpha + \beta$, we define the arithmetical sum of two cardinals as follows:

$*110\cdot02$. $\mu +_c \nu = \hat{\xi}\{(\exists \alpha, \beta) . \mu = \mathrm{N_0c}\text{‘}\alpha . \nu = \mathrm{N_0c}\text{‘}\beta . \xi \,\mathrm{sm}\, (\alpha + \beta)\}$ Df

This defines the "arithmetical sum of two cardinals." (It is not necessary to *significance* that μ and ν should be cardinals, but only that they should be classes of classes. If, however, either is not a cardinal, $\mu +_c \nu = \Lambda$.) It will be observed that, when μ and ν are typically definite, so are α and β in the above definition; but ξ is typically ambiguous, on account of the ambiguity of "sm." Hence $\mu +_c \nu$ is also typically ambiguous.

It will be shown that $\mu +_c \nu$ is always a cardinal, and that, if

$$\mu = \mathrm{N_0c}\text{‘}\alpha . \nu = \mathrm{N_0c}\text{‘}\beta, \text{ then } \mu +_c \nu = \mathrm{Nc}\text{‘}(\alpha + \beta).$$

Hence whenever μ and ν are cardinals other than Λ, $\mu +_c \nu$ is an existent cardinal in some types, though it may be Λ in others.

Two more definitions are required in this number, namely:

$*110\cdot03$. $\mathrm{Nc}\text{‘}\alpha +_c \mu = \mathrm{N_0c}\text{‘}\alpha +_c \mu$ Df

$*110\cdot04$. $\mu +_c \mathrm{Nc}\text{‘}\alpha = \mu +_c \mathrm{N_0c}\text{‘}\alpha$ Df

These definitions are needed in order to apply the definition of $\mu +_c \nu$ to the case in which μ and ν are replaced by typically ambiguous symbols $\mathrm{Nc}\text{‘}\alpha$ and $\mathrm{Nc}\text{‘}\beta$. It does not make any difference to the value of $\mathrm{Nc}\text{‘}\alpha +_c \mathrm{Nc}\text{‘}\beta$ how the ambiguities of $\mathrm{Nc}\text{‘}\alpha$ and $\mathrm{Nc}\text{‘}\beta$ are determined, so long as they are determined in a way that insures $\exists ! \mathrm{Nc}\text{‘}\alpha . \exists ! \mathrm{Nc}\text{‘}\beta$; but if there are types in which either $\mathrm{Nc}\text{‘}\alpha$ or $\mathrm{Nc}\text{‘}\beta$ is Λ, we get $\mathrm{Nc}\text{‘}\alpha +_c \mathrm{Nc}\text{‘}\beta = \Lambda$ in all types if we determine the ambiguities so that $\mathrm{Nc}\text{‘}\alpha = \Lambda$ or $\mathrm{Nc}\text{‘}\beta = \Lambda$. It is in order to exclude such determinations of the ambiguity that the above definitions are required. Also in connection with these definitions and the corresponding definitions $*113\cdot04\cdot05$ and $*116\cdot03\cdot04$ and $*117\cdot02\cdot03$, the convention II T of the prefatory statement must be noted.

The propositions of the present number begin with the properties of $\alpha + \beta$. We show (∗110·11·12) that $\alpha + \beta$ consists of two mutually exclusive parts, which are respectively similar to α and β; we show (∗110·14) that if α and β are mutually exclusive, $\alpha \cup \beta$ is similar to $\alpha + \beta$, and (∗110·15) that if γ and δ are respectively similar to α and β, then $\gamma + \delta$ is similar to $\alpha + \beta$. We show (∗110·16) that $\mathrm{Nc}`(\alpha + \beta)$ consists of all classes which can be divided into two mutually exclusive parts which are respectively similar to α and β.

We then proceed (∗110·2—·252) to the consideration of $\mu +_c \nu$. Here μ and ν are typically definite, and the definition ∗110·02 applies to any typically definite symbols, such as $\mathrm{N_0c}`\alpha$ or $\mathrm{Nc}\,(\eta)`\alpha$. We prove (∗110·21) that if μ and ν are cardinals, their sum consists of all classes similar to some class of the form $\alpha + \beta$, where $\alpha \in \mu \,.\, \beta \in \nu$; we prove (∗110·22) that the sum of $\mathrm{N_0c}`\alpha$ and $\mathrm{N_0c}`\beta$ is $\mathrm{Nc}`(\alpha + \beta)$, and (∗110·25) that if μ and ν are cardinals, their sum is equal to the sum of the "same" cardinals in any other types in which they are not null, *i.e.*

∗110·25. $\vdash : \mu, \nu \in \mathrm{NC} \,.\, \exists !\, \mathrm{sm}_\eta``\mu \,.\, \exists !\, \mathrm{sm}_\zeta``\nu \,.\, \supset .\, \mu +_c \nu = \mathrm{sm}_\eta``\mu +_c \mathrm{sm}_\zeta``\nu$

We then (∗110·3—·351) consider $\mathrm{Nc}`\alpha +_c \mathrm{Nc}`\beta$, to which we apply the definitions ∗110·03·04. We have

∗110·3. $\vdash .\, \mathrm{Nc}`\alpha +_c \mathrm{Nc}`\beta = \mathrm{N_0c}`\alpha +_c \mathrm{N_0c}`\beta = \mathrm{Nc}`(\alpha + \beta)$

whence the other properties of $\mathrm{Nc}`\alpha +_c \mathrm{Nc}`\beta$ follow from previous propositions.

We then have (∗110·4—·44) various propositions on the type of $\mu +_c \nu$ and its existence and kindred matters. The chief of these are

∗110·4. $\vdash : \exists !\, \mu +_c \nu \,.\, \supset .\, \mu, \nu \in \mathrm{NC} - \iota`\Lambda \,.\, \mu, \nu \in \mathrm{N_0C}$

∗110·42. $\vdash .\, \mu +_c \nu \in \mathrm{NC}$

This proposition requires no hypothesis, because, if μ and ν are not both cardinals, $\mu +_c \nu = \Lambda$, and Λ is a cardinal, by ∗102·74.

Our next set of propositions (∗110·5—·57) are concerned with the permutative and associative laws, which are ∗110·51 and ∗110·56 respectively.

We then (∗110·6—·643) consider the addition of 0 or 1, proving (∗110·61) that a cardinal is unchanged by the addition of 0, and (∗110·643) that $1 +_c 1 = 2$.

∗110·01. $\alpha + \beta = \downarrow (\Lambda \cap \beta)``\iota``\alpha \cup (\Lambda \cap \alpha) \downarrow ``\iota``\beta$ Df

∗110·02. $\mu +_c \nu = \hat{\xi}\{(\exists \alpha, \beta) \,.\, \mu = \mathrm{N_0c}`\alpha \,.\, \nu = \mathrm{N_0c}`\beta \,.\, \xi \,\mathrm{sm}\, (\alpha + \beta)\}$ Df

∗110·03. $\mathrm{Nc}`\alpha +_c \mu = \mathrm{N_0c}`\alpha +_c \mu$ Df

∗110·04. $\mu +_c \mathrm{Nc}`\alpha = \mu +_c \mathrm{N_0c}`\alpha$ Df

These definitions are extended by II T of the prefatory statement.

∗110·1. $\vdash :.\, R \in \alpha + \beta \,.\, \equiv : (\exists x) \,.\, x \in \alpha \,.\, R = (\iota`x) \downarrow (\Lambda \cap \beta) \,.\, \mathrm{v} \,.$
$(\exists y) \,.\, y \in \beta \,.\, R = (\Lambda \cap \alpha) \downarrow (\iota`y)$

[∗38·13·131 . (∗110·01)]

$\ast$110·101. $\vdash.(\iota\text{‘}x)\downarrow(\Lambda\cap\beta)\neq(\Lambda\cap\alpha)\downarrow(\iota\text{‘}y)$

Thus when α and β are of the same type, $\mathrm{Nc}`(\alpha + \beta)$ exists at least in the type next above that of $\alpha$ and $\beta$. We cannot prove that it exists in the type of $\alpha$ and $\beta$. *E.g.* suppose the lowest type contained only one member; then if $x$ were that one member, $\mathrm{Nc}`(\iota`x + \iota`x)$ would not exist in the type to which $\iota`x$ belongs; but would exist in the next type, *i.e.* there would not be two individuals, but there would be two classes, namely $\Lambda$ and $\iota`x$, so that $\iota`\Lambda \cup \iota`\iota`x \in \mathrm{Nc}`(\iota`x + \iota`x)$.

A similar proof applies to $\mu^{(2)}$, $\nu^{(2)}$, etc., and to any such derived cardinals whose existence follows from that of μ and ν. The proposition does not hold generally for $\mu_{(1)}$, $\nu_{(1)}$ and other descending derived cardinals, because they may be null when μ and ν exist.

The following proposition (*110·3) is more often used than any other in this number except *110·4.

***110·3.** $\vdash . \mathrm{Nc}^{\prime}\alpha +_c \mathrm{Nc}^{\prime}\beta = \mathrm{N_0c}^{\prime}\alpha +_c \mathrm{N_0c}^{\prime}\beta = \mathrm{Nc}^{\prime}(\alpha + \beta)$ [*110·22.(*110·03·04)]

***110·31.** $\vdash : \gamma \,\mathrm{sm}\, \alpha . \delta \,\mathrm{sm}\, \beta . \supset . \mathrm{Nc}^{\prime}\gamma +_c \mathrm{Nc}^{\prime}\delta = \mathrm{Nc}^{\prime}\alpha +_c \mathrm{Nc}^{\prime}\beta$ [*110·24·3]

The following proposition is frequently used.

***110·32.** $\vdash : \alpha \cap \beta = \Lambda . \supset . \mathrm{Nc}^{\prime}\alpha +_c \mathrm{Nc}^{\prime}\beta = \mathrm{Nc}^{\prime}(\alpha \cup \beta)$ [*110·3·14]

***110·33.** $\vdash : \xi \in \mathrm{Nc}^{\prime}\alpha +_c \mathrm{Nc}^{\prime}\beta . \equiv . (\exists \gamma, \delta) . \gamma \,\mathrm{sm}\, \alpha . \delta \,\mathrm{sm}\, \beta . \gamma \cap \delta = \Lambda . \xi = \gamma \cup \delta$ [*110·3·16]

The above proposition is used in *110·63. We might have used the above to define arithmetical addition, but this method would have been less convenient than the method adopted in this number, both because there would have been more difficulty in dealing with types, and because the existence of $\mathrm{Nc}^{\prime}\alpha +_c \mathrm{Nc}^{\prime}\beta$ (in the types in which it does exist) is less evident with the above definition than with the definitions given in *110·01·02·03·04.

[*110·2] $\equiv . \xi \in \mu +_c \nu : \supset \vdash .$ Prop

The above proposition depends upon the fact that $\mu +_c \nu$ is typically ambiguous, even when μ and ν are typically definite. It is used in the theory of inductive cardinals (*120·32·41·424).

The following propositions are concerned with the commutative and associative laws for arithmetical addition of cardinals.

***110·5.** $\vdash . \beta + \alpha = \mathrm{Cnv}``(\alpha + \beta)$

Dem.

$\vdash . *55·14 . \supset \vdash . \mathrm{Cnv}``(\alpha + \beta) = \Lambda \cap \beta \downarrow ``\iota``\alpha \cup \downarrow \Lambda \cap \alpha``\iota``\beta$
[(*110·01)] $= \beta + \alpha \,.\, \supset \vdash .$ Prop

***110·501.** $\vdash . \beta + \alpha \,\mathrm{sm}\, \alpha + \beta$ [*110·5 . *73·4]

***110·51.** $\vdash . \mu +_c \nu = \nu +_c \mu$ [*110·2·501 . *73·37]

It is not necessary to the truth of the above proposition that μ and ν should be cardinals. If either is not a cardinal, $\mu +_c \nu$ and $\nu +_c \mu$ are both Λ.

The following propositions lead to the associative law (∗110·56).

∗110·52. $\vdash : \xi \operatorname{sm} (\alpha + \beta) + \gamma . \equiv . (\exists \pi, \rho, \sigma) . \pi \operatorname{sm} \alpha . \rho \operatorname{sm} \beta . \sigma \operatorname{sm} \gamma .$
$\pi \cap \rho = \Lambda . \pi \cap \sigma = \Lambda . \rho \cap \sigma = \Lambda . \xi = \pi \cup \rho \cup \sigma$

Dem.

$\vdash . *110·152 . \supset \vdash :. \xi \operatorname{sm} (\alpha + \beta) + \gamma . \equiv : (\exists \eta, \sigma) . \eta \operatorname{sm} (\alpha + \beta) .$
$\sigma \operatorname{sm} \gamma . \eta \cap \sigma = \Lambda . \xi = \eta \cup \sigma :$

[∗110·152] $\equiv : (\exists \pi, \rho, \eta, \sigma) . \pi \operatorname{sm} \alpha . \rho \operatorname{sm} \beta . \pi \cap \rho = \Lambda . \eta = \pi \cup \rho .$
$\sigma \operatorname{sm} \gamma . \eta \cap \sigma = \Lambda . \xi = \eta \cup \sigma :$

[∗13·195.∗22·68.∗24·32] $\equiv : (\exists \pi, \rho, \sigma) . \pi \operatorname{sm} \alpha . \rho \operatorname{sm} \beta . \sigma \operatorname{sm} \gamma . \pi \cap \rho = \Lambda .$

[∗13·171] $\supset . (\mu +_c \nu) +_c \varpi = \mu +_c (\nu +_c \varpi)$ (2)
$\vdash . (1) . (2) . \supset \vdash .$ Prop

This is the associative law for arithmetical addition. It will be seen that, like the commutative law, it does not require that μ, ν, ϖ should be cardinals.

∗110·561. $\mu +_c \nu +_c \varpi = (\mu +_c \nu) +_c \varpi$ Df

∗110·57. $\vdash . (\mu +_c \nu) +_c (\varpi +_c \rho) = \mu +_c \nu +_c \varpi +_c \rho$ [∗110·56 . (∗110·561)]

The following propositions, concerning the addition of 0 or 1, are used frequently in dealing with inductive cardinals (*120).

***110·6.** $\vdash : \mu \epsilon \mathrm{NC} . \supset . \mu +_c 0 = \mathrm{sm}``\mu$

Dem.

$\vdash . *101 \cdot 11 . *110 \cdot 21 . \supset$

$\vdash :. \mathrm{Hp} . \supset : \xi \epsilon \mu +_c 0 . \equiv . (\exists \alpha, \beta) . \alpha \epsilon \mu . \beta \epsilon 0 . \xi \,\mathrm{sm}\, (\alpha + \beta) .$

[*54·102] $\equiv . (\exists \alpha) . \alpha \epsilon \mu . \xi \,\mathrm{sm}\, (\alpha + \Lambda) .$

[*110·152] $\equiv . (\exists \alpha, \gamma, \delta) . \alpha \epsilon \mu . \gamma \,\mathrm{sm}\, \alpha . \delta \,\mathrm{sm}\, \Lambda . \gamma \cap \delta = \Lambda . \xi = \gamma \cup \delta .$

[*73·47] $\equiv . (\exists \alpha, \gamma) . \alpha \epsilon \mu . \gamma \,\mathrm{sm}\, \alpha . \xi = \gamma .$

[*13·195] $\equiv . (\exists \alpha) . \alpha \epsilon \mu . \xi \,\mathrm{sm}\, \alpha .$

[*37·1] $\equiv . \xi \epsilon \mathrm{sm}``\mu :. \supset \vdash . \mathrm{Prop}$

When μ is a typically definite cardinal, $\mathrm{sm}``\mu$ is the same cardinal rendered typically ambiguous; when $\mu$ is a typically ambiguous cardinal, $\mathrm{sm}``\mu$ is μ. In place of the above proposition, we *might* write $\mu \epsilon \mathrm{NC} . \supset . \mu +_c 0 = \mu$; this would be true whenever the ambiguity of $\mu +_c 0$ was so determined as to make it significant. But the above form gives more information.

***110·61.** $\vdash . \mathrm{Nc}`\alpha +_c 0 = \mathrm{Nc}`\alpha$

Dem.

$\vdash . *101 \cdot 1 . \supset \vdash . \mathrm{Nc}`\alpha +_c 0 = \mathrm{Nc}`\alpha +_c \mathrm{Nc}`\Lambda$

[*110·32] $= \mathrm{Nc}`(\alpha \cup \Lambda)$

[*24·24] $= \mathrm{Nc}`\alpha . \supset \vdash . \mathrm{Prop}$

In this proposition, $\mathrm{Nc}`\alpha$ is typically ambiguous; hence we escape the necessity of putting $\mathrm{sm}``\mathrm{Nc}`\alpha$ on the right, as we should have to do if $\mathrm{Nc}`\alpha$ were typically definite. We can deduce *110·61 from *110·6 as follows:

$\vdash . *110 \cdot 3 . \supset \vdash . \mathrm{Nc}`\alpha +_c 0 = \mathrm{N_0c}`\alpha +_c 0$

[*110·6] $= \mathrm{sm}``\mathrm{N_0c}`\alpha$

[*103·4] $= \mathrm{Nc}`\alpha$

We have to travel via $\mathrm{N_0c}`\alpha$ in this proof, in order to avoid the possibility of a typical determination of $\mathrm{Nc}`\alpha$ which would make $\mathrm{Nc}`\alpha = \Lambda$. It is for the same reason that we cannot put "$\mathrm{sm}``\mathrm{Nc}`\alpha = \mathrm{Nc}`\alpha$"; for if the first $\mathrm{Nc}`\alpha$ is determined to a type in which $\mathrm{Nc}`\alpha = \Lambda$, while the second is not, this equation becomes false.

***110·62.** $\vdash : \mu +_c \nu = 0 . \equiv . \mu = 0 . \nu = 0$

Dem.

$\vdash . *103 \cdot 27 . *101 \cdot 11 \cdot 13 . \supset \vdash . 0 = \mathrm{N_0c}`\Lambda$ (1)

$\vdash . (1) . *110 \cdot 43 . \supset$

$\vdash :. \mu +_c \nu = 0 . \equiv : \Lambda \epsilon \mu +_c \nu :$

[*110·202] $\equiv : \exists ! \mu . \exists ! \nu : (\exists \gamma, \delta) . \mu = \mathrm{Nc}`\gamma . \nu = \mathrm{Nc}`\delta . \gamma \cap \delta = \Lambda . \gamma \cup \delta = \Lambda :$

[*24·32.*13·22] $\equiv : \exists ! \mu . \exists ! \nu : \mu = \mathrm{Nc}`\Lambda . \nu = \mathrm{Nc}`\Lambda :$

[*101·1·12] $\equiv : \mu = 0 . \nu = 0 :. \supset \vdash . \mathrm{Prop}$

***110·63.** $\vdash . \mathrm{Nc}`\alpha +_c 1 = \hat{\xi}\{(\exists\gamma, y) . \gamma \,\mathrm{sm}\, \alpha . y \sim\in \gamma . \xi = \gamma \cup \iota`y\}$

Dem.

$\vdash . *101{\cdot}2 . \supset$

$\vdash . \mathrm{Nc}`\alpha +_c 1 = \mathrm{Nc}`\alpha +_c \mathrm{Nc}`\iota`x$

[*110·33] $= \hat{\xi}\{(\exists\gamma, \delta) . \gamma \,\mathrm{sm}\, \alpha . \delta \,\mathrm{sm}\, \iota`x . \gamma \cap \delta = \Lambda . \xi = \gamma \cup \delta\}$

[*73·45] $= \hat{\xi}\{(\exists\gamma, \delta) . \gamma \,\mathrm{sm}\, \alpha . \delta \in 1 . \gamma \cap \delta = \Lambda . \xi = \gamma \cup \delta\}$

[*52·1] $= \hat{\xi}\{(\exists\gamma, \delta, y) . \gamma \,\mathrm{sm}\, \alpha . \delta = \iota`y . \gamma \cap \delta = \Lambda . \xi = \gamma \cup \delta\}$

[*13·195.*51·211] $= \hat{\xi}\{(\exists\gamma, y) . \gamma \,\mathrm{sm}\, \alpha . y \sim\in \gamma . \xi = \gamma \cup \iota`y\} . \supset \vdash . \mathrm{Prop}$

The above proposition is much used in the theory of finite and infinite, both cardinal and ordinal. It connects mathematical induction for inductive cardinals with mathematical induction for inductive classes (cf. *120).

***110·631.** $\vdash : \mu \in \mathrm{NC} . \supset . \mu +_c 1 = \hat{\xi}\{(\exists\gamma, y) . \gamma \in \mathrm{sm}``\mu . y \sim\in \gamma . \xi = \gamma \cup \iota`y\}$

Dem.

$\vdash . *110{\cdot}211 . *101{\cdot}21 . \supset$

$\vdash : \mathrm{Hp} . \supset . \mu +_c 1 = \hat{\xi}\{(\exists\gamma, \delta) . \gamma \in \mathrm{sm}``\mu . \delta \in \mathrm{sm}``1 . \gamma \cap \delta = \Lambda . \xi = \gamma \cup \delta\}$

[*101·28] $= \hat{\xi}\{(\exists\gamma, \delta) . \gamma \in \mathrm{sm}``\mu . \delta \in 1 . \gamma \cap \delta = \Lambda . \xi = \gamma \cup \delta\}$

[*52·1.*51·211] $= \hat{\xi}\{(\exists\gamma, y) . \gamma \in \mathrm{sm}``\mu . y \sim\in \gamma . \xi = \gamma \cup \iota`y\} : \supset \vdash . \mathrm{Prop}$

The proposition

$$\mu \in \mathrm{NC} . \supset . \mu +_c 1 = \hat{\xi}\{(\exists\gamma, y) . \gamma \in \mu . y \sim\in \gamma . \xi \,\mathrm{sm}\, \gamma \cup \iota`y\}$$

which might at first sight seem demonstrable, will only be true universally if the total number of objects in any one type is not finite. For suppose α is a type, and $\mu = \mathrm{N_0c}`\alpha$. Then if $\alpha$ is a finite class, $\mu = \iota`\alpha$. Hence $\gamma \in \mu . \supset_{\gamma, y} . y \in \gamma$. Hence $\hat{\xi}\{(\exists\gamma, y) . \gamma \in \mu . y \sim\in \gamma . \xi \,\mathrm{sm}\, (\gamma \cup \iota`y)\} = \Lambda$ in all types. But $\mu +_c 1$ will exist in all types higher than that of γ. If on the other hand the number of entities in α is infinite, we shall have

$$y \in \alpha . \supset . \alpha - \iota`y \in \mathrm{Nc}`\alpha . y \sim\in \alpha - \iota`y.$$

Hence in this case the above proposition will be true universally.

***110·632.** $\vdash : \mu \in \mathrm{NC} . \supset . \mu +_c 1 = \hat{\xi}\{(\exists y) . y \in \xi . \xi - \iota`y \in \mathrm{sm}``\mu\}$

Dem.

$\vdash . *110{\cdot}631 . *51{\cdot}211{\cdot}22 . \supset$

$\vdash : \mathrm{Hp} . \supset . \mu +_c 1 = \hat{\xi}\{(\exists\gamma, y) . \gamma \in \mathrm{sm}``\mu . y \in \xi . \gamma = \xi - \iota`y\}$

[*13·195] $= \hat{\xi}\{(\exists y) . y \in \xi . \xi - \iota`y \in \mathrm{sm}``\mu\} : \supset \vdash . \mathrm{Prop}$

***110·64.** $\vdash . 0 +_c 0 = 0$ [*110·62]

***110·641.** $\vdash . 1 +_c 0 = 0 +_c 1 = 1$ [*110·51·61 . *101·2]

***110·642.** $\vdash . 2 +_c 0 = 0 +_c 2 = 2$ [*110·51·61 . *101·31]

***110·643.** $\vdash . 1 +_0 1 = 2$

Dem.

$\vdash . *110·632 . *101·21·28 . \supset$

$\vdash . 1 +_0 1 = \hat{\xi}\{(\exists y) . y \in \xi . \xi - \iota`y \in 1\}$

$[*54·3] \quad = 2 . \supset \vdash . \text{Prop}$

The above proposition is occasionally useful. It is used at least three times, in *113·66 and *120·123·472.

*110·7·71 are required for proving *110·72, and *110·72 is used in *117·3, which is a fundamental proposition in the theory of greater and less.

***110·7.** $\vdash : \beta \subset \alpha . \supset . (\exists \mu) . \mu \in \text{NC} . \text{Nc}`\alpha = \text{Nc}`\beta +_0 \mu$

Dem.

$\vdash . *24·411·21 . \supset \vdash : \text{Hp} . \supset . \alpha = \beta \cup (\alpha - \beta) . \beta \cap (\alpha - \beta) = \Lambda .$

$[*110·32] \qquad \supset . \text{Nc}`\alpha = \text{Nc}`\beta +_0 \text{Nc}`(\alpha - \beta) : \supset \vdash . \text{Prop}$

***110·71.** $\vdash : (\exists \mu) . \text{Nc}`\alpha = \text{Nc}`\beta +_0 \mu . \supset . (\exists \delta) . \delta \,\text{sm}\, \beta . \delta \subset \alpha$

Dem.

$\vdash . *100·3 . *110·4 . \supset$

$\vdash : \text{Nc}`\alpha = \text{Nc}`\beta +_0 \mu . \supset . \mu \in \text{NC} - \iota`\Lambda \qquad (1)$

$\vdash . *110·3 . \supset \vdash : \text{Nc}`\alpha = \text{Nc}`\beta +_0 \text{Nc}`\gamma . \equiv . \text{Nc}`\alpha = \text{Nc}`(\beta + \gamma) .$

$[*100·3·31] \qquad \supset . \alpha \,\text{sm}\, (\beta + \gamma) .$

$[*73·1] \qquad \supset . (\exists R) . R \in 1 \rightarrow 1 . \text{D}`R = \alpha . \text{Ɑ}`R = \downarrow \Lambda_\gamma``\iota``\beta \cup \Lambda_\beta \downarrow ``\iota``\gamma .$

$[*37·15] \qquad \supset . (\exists R) . R \in 1 \rightarrow 1 . \downarrow \Lambda_\gamma``\iota``\beta \subset \text{Ɑ}`R . R`` \downarrow \Lambda_\gamma``\iota``\beta \subset \alpha .$

$[*110·12 . *73·22] \supset . (\exists \delta) . \delta \subset \alpha . \delta \,\text{sm}\, \beta \qquad (2)$

$\vdash . (1) . (2) . \supset \vdash . \text{Prop}$

The above proof depends upon the fact that "$\text{Nc}`\alpha$" and "$\text{Nc}`\beta +_0 \mu$" are typically ambiguous, and therefore, when they are asserted to be equal, this must hold in *any* type, and therefore, in particular, in that type for which we have $\alpha \in \text{Nc}`\alpha$, *i.e.* for $\text{N}_0\text{c}`\alpha$. This is why the use of *100·3 is legitimate.

***110·72.** $\vdash : (\exists \delta) . \delta \,\text{sm}\, \beta . \delta \subset \alpha . \equiv . (\exists \mu) . \mu \in \text{NC} . \text{Nc}`\alpha = \text{Nc}`\beta +_0 \mu$

Dem.

$\vdash . *100·321 . *110·7 . \supset$

$\vdash :. \delta \,\text{sm}\, \beta . \delta \subset \alpha . \supset : \text{Nc}`\delta = \text{Nc}`\beta : (\exists \mu) . \mu \in \text{NC} . \text{Nc}`\alpha = \text{Nc}`\delta +_0 \mu :$

$\vdash . (1) . *110·71 . \supset \vdash . \text{Prop}$

$*$111. DOUBLE SIMILARITY

Summary of $*$111.

The arithmetical properties of a class, so far as these do not require or assume that it is a class of classes, are the same for any similar class. But a class of classes has many arithmetical properties which it does not share with all similar classes of classes. For example, if κ is a class of classes, the number of members of $s`\kappa$ is an arithmetical property of κ, but it is obvious that this is not determined by the number of members of κ, but requires also a knowledge of the numbers of members of members of κ. For example, let κ consist of the two members α and β, and let λ consist of γ and δ. Then $\kappa \operatorname{sm} \lambda$; but in order to be able to infer $s`\kappa \operatorname{sm} s`\lambda$, we require $\kappa, \lambda \epsilon \mathrm{Cls}^2\,\mathrm{excl}$ and $\alpha \operatorname{sm} \gamma \,.\, \beta \operatorname{sm} \delta$ or $\alpha \operatorname{sm} \delta \,.\, \beta \operatorname{sm} \gamma$ or some such further datum. The relation of "double similarity," to be defined in the present number, is a relation between classes of classes, which, when it holds between κ and λ, insures that all the arithmetical properties of κ and λ are the same, *e.g.* we have (in particular) $\mathrm{Nc}`s`\kappa = \mathrm{Nc}`s`\lambda$ and $\mathrm{Nc}`\epsilon_\Delta`\kappa = \mathrm{Nc}`\epsilon_\Delta`\lambda$. This relation we denote by "sm sm," which is to be read as one symbol. It is defined as follows: We define first the class of "double correlators" of κ and λ, which we denote by "$\kappa \,\overline{\operatorname{sm}}\,\overline{\operatorname{sm}}\, \lambda$," and of which the definition is

$$*111\cdot01.\quad \kappa \,\overline{\operatorname{sm}}\,\overline{\operatorname{sm}}\, \lambda = (1 \to 1) \cap \overleftarrow{\mathrm{C}}`s`\lambda \cap \hat{T}(\kappa = T_\epsilon``\lambda) \quad \mathrm{Df}$$

so that

$$\vdash : T \epsilon \kappa \,\overline{\operatorname{sm}}\,\overline{\operatorname{sm}}\, \lambda \,.\equiv .\, T \epsilon 1 \to 1 \,.\, \mathrm{C}`T = s`\lambda \,.\, \kappa = T_\epsilon``\lambda.$$

We then define "$\kappa \operatorname{sm} \operatorname{sm} \lambda$" as meaning that $\kappa \,\overline{\operatorname{sm}}\,\overline{\operatorname{sm}}\, \lambda$ is not null, *i.e.* that there is at least one double correlator of κ and λ.

To illustrate the nature of a double correlator, let us suppose that κ consists of the two classes α_1 and α_2, and that α_1 consists of x_{11}, x_{12}, while α_2 consists of x_{21}, x_{22}, x_{23}. Similarly let λ consist of β_1 and β_2, while β_1 consists of y_{11}, y_{12} and β_2 consists of y_{21}, y_{22}, y_{23}. Now let T correlate each x with the y having the same two suffixes. Then T is a one-one, and its converse domain is $s`\lambda$. Moreover $T_\epsilon`\beta_1$ (which is $T``\beta_1) = \alpha_1$, and $T_\epsilon`\beta_2 = \alpha_2$, so that $T_\epsilon``\lambda = \kappa$. Thus T is a double correlator according to the definition.

The essential characteristic of a double correlator T is that (1) T is a correlator of $s`\kappa$ and $s`\lambda$, (2) $T_\epsilon \upharpoonright \lambda$ is a correlator of κ and λ. If we write S in place of $T_\epsilon \upharpoonright \lambda$, then if $\beta \epsilon \lambda$, we have $S`\beta \epsilon \kappa$; moreover $T \upharpoonright \beta$ is a correlator of $S`\beta$ and β. Thus κ and λ are similar classes of similar classes. They are not merely this, however, for we not only know that $S`\beta$ is similar to β, but

we know a particular correlator of $S`\beta$ and β, namely $T \upharpoonright \beta$. This is essential to the use of double similarity, as will appear shortly.

Let us consider the relation between κ and λ which consists in their being similar classes of similar classes. This means that there is a correlator S of κ and λ, such that, if $\beta \epsilon \lambda$, $S`\beta$ is similar to β. That is to say, we are to consider the hypothesis

$$(\exists S) \,.\, S \epsilon 1 \rightarrow 1 \,.\, \mathrm{D}`S = \kappa \,.\, \text{Ꮖ}`S = \lambda \,.\, S \mathrel{\mathsf{C}} \mathrm{sm}$$

or, as it may be more briefly expressed,

$$\exists ! \, \kappa \, \overline{\mathrm{sm}} \, \lambda \cap \mathrm{Rl}`\mathrm{sm}.$$

Let us assume $S \epsilon \kappa \, \overline{\mathrm{sm}} \, \lambda \cap \mathrm{Rl}`\mathrm{sm}$. If we attempt to prove (say) that $s`\kappa$ is similar to $s`\lambda$, we find that we are forced to assume the multiplicative axiom, unless κ and λ are finite. This necessity arises as follows. Let us put

$$\mathrm{Crp}\,(S)`\beta = (S`\beta) \, \overline{\mathrm{sm}} \, \beta,$$

where "Crp" stands for "correspondence." Then we know that whenever $\beta \epsilon \lambda$, $\mathrm{Crp}\,(S)`\beta$ is not null. Further it is easy to prove that, if $\kappa$ and $\lambda$ are classes of mutually exclusive classes, and if we can pick out one representative member of $\mathrm{Crp}\,(S)`\beta$ for each value of β which is a member of λ, then the relational sum of all these representative correlations gives us a correlator of $s`\kappa$ and $s`\lambda$. That is, we have

$$\vdash : \kappa, \lambda \epsilon \mathrm{Cls}^2 \,\mathrm{excl} \,.\, S \epsilon \kappa \, \overline{\mathrm{sm}} \, \lambda \cap \mathrm{Rl}`\mathrm{sm} \,.\, R \epsilon \epsilon_\Delta`\mathrm{Crp}(S)``\lambda \,.\, \supset .\, \dot{s}`\mathrm{D}`R \epsilon (s`\kappa) \, \overline{\mathrm{sm}} \, (s`\lambda).$$

But in order to infer hence $s`\kappa \,\mathrm{sm}\, s`\lambda$, we need $\exists ! \, \epsilon_\Delta`\mathrm{Crp}\,(S)``\lambda$, *i.e.* we need to be able to pick out a particular correlator for each pair of similar classes $S`\beta$ and $\beta$. This, however, cannot be done in general without assuming the multiplicative axiom. It follows that we must not define two classes as having double similarity when $\exists ! \, \kappa \, \overline{\mathrm{sm}} \, \lambda \cap \mathrm{Rl}`\mathrm{sm}$, but must give a definition which enables us to specify a particular correlator for each pair of similar classes. This is what is effected by the above definition of double correlators, where our S is given as of the form $T_\epsilon \upharpoonright \lambda$, where $T \epsilon 1 \rightarrow 1 \,.\, \text{Ꮖ}`T = s`\lambda$. If the multiplicative axiom is assumed, but in general not otherwise, we have (*111·5)

$$\kappa, \lambda \epsilon \mathrm{Cls}^2 \,\mathrm{excl} \,.\, \supset : \kappa \,\mathrm{sm}\,\mathrm{sm}\, \lambda \,.\equiv .\, \exists ! \, \kappa \, \overline{\mathrm{sm}} \, \lambda \cap \mathrm{Rl}`\mathrm{sm}.$$

In the present number, we shall begin with various properties of double correlators. We prove (*111·11) that T is a double correlator of κ and λ when, and only when, T is a correlator of $s`\kappa$ and $s`\lambda$, and $T_\epsilon \upharpoonright \lambda$ is a correlator of κ and λ. We prove (*111·112) that in the same hypothesis, $T_\epsilon \upharpoonright \lambda \epsilon \kappa \, \overline{\mathrm{sm}} \, \lambda \cap \mathrm{Rl}`\mathrm{sm}$. We prove (*111·13) that $I \upharpoonright s`\lambda$ is a double correlator of λ with itself; that (*111·131) if T is a double correlator of κ and λ, $\breve{T}$ is a double correlator of λ and κ; that (*111·132) if S, T are double correlators of κ with λ and of λ with μ respectively, $S | T$ is a double correlator of κ with μ. Hence it follows (*111·45·451·452) that double similarity is reflexive, symmetrical, and transitive.

We then proceed (*111·2—·34) to consider $\text{Crp}(S)``\lambda$, where it is to be supposed that $S$ is a correlator of $S``\lambda$ and λ, and that $S`\beta$ is similar to β if $\beta \epsilon \lambda$. We prove

*111·32. $\vdash : \lambda, S``\lambda \epsilon \text{Cls}^2 \text{excl} . S \epsilon 1 \rightarrow 1 . R \epsilon \epsilon_\Delta`\text{Crp}(S)``\lambda . M = \dot{s}`\text{D}`R . \supset .$
$M \epsilon 1 \rightarrow 1 . \text{ɑ}`M = s`\lambda . S``\lambda = M_\epsilon``\lambda . S \upharpoonright \lambda = M_\epsilon \upharpoonright \lambda$

Thus in the case supposed, M is a double correlator of $S``\lambda$ and λ. Thus

*111·322. $\vdash : \kappa, \lambda \epsilon \text{Cls}^2 \text{excl} . S \epsilon \kappa \,\overline{\text{sm}}\, \lambda . R \epsilon \epsilon_\Delta`\text{Crp}(S)``\lambda . M = \dot{s}`\text{D}`R . \supset .$
$M \epsilon \kappa \,\overline{\text{sm}}\,\overline{\text{sm}}\, \lambda . S = M_\epsilon \upharpoonright \lambda$

We then proceed (*111·4—·47) to various propositions on "sm sm," and finally (*111·5·51·53) state three propositions which assume the multiplicative axiom, namely

*111·5. If $\kappa, \lambda \epsilon \text{Cls}^2 \text{excl}$, then $\kappa \,\text{sm sm}\, \lambda . \equiv . \exists ! \kappa \,\overline{\text{sm}}\, \lambda \cap \text{Rl}`\text{sm}$.

*111·51. In the same case, $\exists ! \kappa \,\overline{\text{sm}}\, \lambda \cap \text{Rl}`\text{sm} . \supset . s`\kappa \,\text{sm}\, s`\lambda$, *i.e.* if κ and λ are similar classes of mutually exclusive similar classes, their sums are similar.

*111·53. In the same case, if $\kappa, \lambda \epsilon \text{Cls}^2 \text{excl}$, $\kappa \,\text{sm sm}\, \lambda$. Hence the multiplicative axiom implies that two classes of μ mutually exclusive classes each of which has ν terms, have the same number of terms in their sum.

$\vdash . (1) . (2) . *80{\cdot}14 . \supset \vdash . \mathrm{Prop}$

The class $(\alpha \uparrow \beta)_\Delta`\beta$ is important, being the class of Cantor's "Belegungen," used by him to define exponentiation; we have in fact

$$\mathrm{Nc}`(\alpha \uparrow \beta)_\Delta`\beta = (\mathrm{Nc}`\alpha)^{\mathrm{Nc}`\beta}.$$

Thus the above proposition shows that $\mathrm{Nc}`(\alpha \,\overline{\mathrm{sm}}\, \beta)$ is less than or equal to $(\mathrm{Nc}`\alpha)^{\mathrm{Nc}`\beta}$; and since, whenever it is not zero, $\mathrm{Nc}`\alpha = \mathrm{Nc}`\beta$, it is less than or equal to

$$(\mathrm{Nc}`\alpha)^{\mathrm{Nc}`\alpha}.$$

The following propositions lead up to $*111{\cdot}32{\cdot}33{\cdot}34$:

$*111{\cdot}2$. $\vdash : \mathrm{E} ! \,S`\beta . \supset . \mathrm{Crp}\,(S)`\beta = (S`\beta) \,\overline{\mathrm{sm}}\, \beta \qquad [*14{\cdot}28 . (*111{\cdot}02)]$

*112. THE ARITHMETICAL SUM OF A CLASS OF CLASSES

Summary of *112.

In this number, we return to the arithmetical operations. The definition of addition in *110 was only applicable to a finite number of summands, because the summands had to be enumerated. In the present number, we define the arithmetical sum of a class of classes, so that the summands are given as the members of a class, and do not require to be enumerated. Hence the definition in this number is as applicable to an infinite number of summands as to a finite number.

If κ is a class of mutually exclusive classes, the number of $s\text{‘}\kappa$ will be the sum of the numbers of members of κ; *i.e.* if we write "$\Sigma\mathrm{Nc}\text{‘}\kappa$" for the sum of the numbers of members of κ,

$$\kappa \in \mathrm{Cls}^2\,\mathrm{excl} \,.\supset .\, \mathrm{Nc}\text{‘}s\text{‘}\kappa = \Sigma\mathrm{Nc}\text{‘}\kappa.$$

But when the members of κ are not mutually exclusive, a term x which is a member of two members (say α and β) of κ has to be counted twice over in obtaining the arithmetical sum of κ, whereas in the logical sum x is only counted once. Thus we need a construction which shall duplicate x, taking it first as a member of α, and then as a member of β. This is effected if we replace x first by $x \downarrow \alpha$, and then by $x \downarrow \beta$. In fact, $x \downarrow \alpha$ has the kind of arithmetical properties which we mean to secure when we speak of "x considered as a member of α"—a phrase which, as it stands, does not serve our purpose, for x is simply x however we may choose to consider it. Thus we replace α by $\downarrow \alpha\text{‘‘}\alpha$ and β by $\downarrow \beta\text{‘‘}\beta$ and so on; *i.e.* (using *85·5), we replace α by $\epsilon \,\underline{\downarrow}\, \alpha$ and β by $\epsilon \,\underline{\downarrow}\, \beta$ and so on. These new classes are similar to α and β and so on, and are mutually exclusive. Hence their *logical* sum has the number of terms which is wanted for the *arithmetical* sum of the members of κ. Thus we put

$$\Sigma\text{‘}\kappa = s\text{‘}\epsilon \,\underline{\downarrow}\text{‘‘}\kappa \quad \mathrm{Df},$$

$$\Sigma\mathrm{Nc}\text{‘}\kappa = \mathrm{Nc}\text{‘}\Sigma\text{‘}\kappa \quad \mathrm{Df}.$$

With regard to the second of these definitions, it is to be observed that $\Sigma\mathrm{Nc}\text{‘}\kappa$ is not a function of $\mathrm{Nc}\text{‘‘}\kappa$, unless no two members of κ are similar; for $\mathrm{Nc}\text{‘‘}\kappa$ cannot contain the same number twice over. For the same reason, if λ is a class of cardinals, and we define "$\mathrm{Sum}\text{‘}\lambda$," we do not get what is wanted for arithmetical addition, because our definition will not enable us to deal with summations in which there are numbers that are repeated. We could, if it were worth while, define "$\mathrm{Sum}\text{‘}\lambda$" as follows: Take a class of classes κ, consisting of one class having each number which is a member of λ, *i.e.* let κ

be a selection from λ; then $\Sigma`\kappa$ will have the required number of terms. *I.e.* we might put

$$\text{Sum}`\lambda = \hat{\xi}\{(\exists\kappa) . \kappa \epsilon D``\epsilon_\Delta`\lambda . \xi \text{ sm } \Sigma`\kappa\} \quad \text{Df.}$$

But since this definition is only available for sums in which no number is repeated, it is not worth while to introduce it.

In this number we prove the following propositions among others.

***112·15.** $\vdash : \kappa \epsilon \text{Cls}^2 \text{excl} . \supset . s`\kappa \epsilon \Sigma\text{Nc}`\kappa$

This is an extension of *110·32.

***112·17.** $\vdash : \kappa \text{ sm sm } \lambda . \supset . \Sigma\text{Nc}`\kappa = \Sigma\text{Nc}`\lambda . \Sigma`\kappa \text{ sm } \Sigma`\lambda$

The chief point in the above proposition is that it does not require $\kappa, \lambda \epsilon \text{Cls}^2 \text{excl}$.

*112·2—·24 are concerned with the use of the multiplicative axiom and the propositions of *111 in which it appears as hypothesis. We have

***112·22.** $\vdash :. \text{Mult ax} . \supset : \exists ! (\epsilon \downarrow``\kappa) \overline{\text{sm}} (\epsilon \downarrow``\lambda) \cap \text{Rl}`\text{sm} . \supset . \Sigma\text{Nc}`\kappa = \Sigma\text{Nc}`\lambda$

whence we derive the proposition

***112·24.** $\vdash :. \text{Mult ax} . \supset : \mu, \nu \epsilon \text{NC} . \kappa, \lambda \epsilon \mu \cap \text{Cl}`\nu . \supset . \Sigma\text{Nc}`\kappa = \Sigma\text{Nc}`\lambda$

I.e. assuming the multiplicative axiom, two classes which each consist of μ classes of ν terms each have the same number of terms in their sum. This number would naturally be defined as μ multiplied by ν, but owing to the necessity of the multiplicative axiom in this proposition, we have selected a different definition of multiplication (*113) which does not depend upon the multiplicative axiom. The reader should observe that the similarity of two classes, each of which consists of μ mutually exclusive sets of ν terms, cannot be proved in general without the multiplicative axiom.

The remaining propositions of this number give properties of Σ in special cases. We prove that $\Sigma`\Lambda = \Lambda$ (*112·3), that $\Sigma\text{Nc}`\iota`\alpha = \text{Nc}`\alpha$ (*112·321), that $\alpha \neq \beta . \supset . \Sigma\text{Nc}`(\iota`\alpha \cup \iota`\beta) = \text{Nc}`\alpha +_c \text{Nc}`\beta$ (*112·34), which connects the definition of addition in this number with that in *110. Finally we prove the general associative law for addition, in the following two forms:

***112·41.** $\vdash . s`\Sigma``\lambda = \Sigma`s`\lambda$

***112·43.** $\vdash : \lambda \epsilon \text{Cls}^2 \text{excl} . \supset . \text{Nc}`\Sigma`\Sigma``\lambda = \text{Nc}`\Sigma`s`\lambda$

The following proposition is a lemma for $*112\cdot153$, which is required for $*112\cdot16$. $*112\cdot16$ in turn is used in $*112\cdot17$, which is a fundamental proposition in the theory of addition.

$*112\cdot152$. $\vdash : T \epsilon 1 \to \text{Cls} . \beta \subset \text{Ɑ}\text{‘}T . \supset . (T \| \breve{T}_\epsilon)\text{‘‘}\epsilon \overline{\downarrow} \beta = \epsilon \overline{\downarrow} (T\text{‘‘}\beta)$

Dem.

$\vdash . *37\cdot6 . *85\cdot601 . \supset \vdash . (T \| \breve{T}_\epsilon)\text{‘‘}\epsilon \overline{\downarrow} \beta = \hat{R}\{(\exists y) . y \epsilon \beta . R = (T \| \breve{T}_\epsilon)\text{‘}(y \downarrow \beta)\}$ (1)

$\vdash . (1) . *55\cdot61 . \supset$

$\vdash : \text{Hp} . \supset . (T \| \breve{T}_\epsilon)\text{‘‘}\epsilon \overline{\downarrow} \beta = \hat{R}\{(\exists y) . y \epsilon \beta . R = (T\text{‘}y) \downarrow (T_\epsilon\text{‘}\beta)\}$

$[*37\cdot11] \quad = \hat{R}\{(\exists y) . y \epsilon \beta . R = (T\text{‘}y) \downarrow (T\text{‘‘}\beta)\}$

$[*38\cdot131] \quad = \downarrow (T\text{‘‘}\beta)\text{‘‘}(T\text{‘‘}\beta)$

$[*85\cdot601] \quad = \epsilon \overline{\downarrow} (T\text{‘‘}\beta) : \supset \vdash . \text{Prop}$

In the following proposition, we have a double correlator of a sort which will frequently occur in cardinal arithmetic, namely $T \| \breve{T}_\epsilon$ with its converse domain limited, where T is a given double correlator (or single correlator, on other occasions). As appears from the propositions used in the above proof of $*112\cdot152$, if T is a correlator whose converse domain includes β and has y as a member, $(T \| \breve{T}_\epsilon)\text{‘}(y \downarrow \beta) = (T\text{‘}y) \downarrow (T\text{‘‘}\beta)$. Thus $T \| \breve{T}_\epsilon$ is an operation which, when operating on suitable relations of individuals to classes (including selectors), turns the individuals into their correlates and the classes into the classes of their members' correlates. This is why it is a useful relation.

This proposition establishes the agreement of the two definitions of addition, namely that in *110 and that in *112. It will be seen that the definition of *112 is inapplicable to the addition of a class to itself, if this is to give the double of the class, instead of (like logical addition) simply reproducing the class. Hence the need of the condition $\alpha \neq \beta$ in the above proposition.

The above is the associative law for arithmetical addition.

$*113$. ON THE ARITHMETICAL PRODUCT OF TWO CLASSES OR OF TWO CARDINALS

Summary of $*113$.

In this number, we give a definition of multiplication which can be extended to any finite number of factors, but not to an infinite number of factors. We define first the arithmetical class-product of two classes α and β, and thence the product of two cardinals μ and ν as the number of terms in the product of α and β when α has μ terms and β has ν terms. In $*114$, we shall give a definition of multiplication which is not restricted to a finite number of factors. The advantages of the definition to be given in this number are, that it does not require the factors to be of the same type, and that it enables us to multiply a class by itself without (as in logical addition and multiplication) simply reproducing the class in question. The disadvantage of the definition in this number is the impossibility of extending it to an infinite number of factors.

The arithmetical class-product of two classes α and β, which we denote by $\beta \times \alpha$[*], is the class of all ordinal couples which take their referent from α and their relatum from β, *i.e.* it is the class of all such relations as $x \downarrow y$, where $x \in \alpha$ and $y \in \beta$. For a given y, the class of couples we obtain is $\downarrow y``\alpha$, which is similar to α; and the number of such classes, for varying y, is $\mathrm{Nc}`\beta$. Thus we have $\mathrm{Nc}`\beta$ classes of $\mathrm{Nc}`\alpha$ couples, and $\beta \times \alpha$ is the logical sum of these classes of couples. The class of such classes as $\downarrow y``\alpha$, where $y \in \beta$, is important again in connection with exponentiation; we have $\downarrow y``\alpha = \alpha \underset{,,}{\downarrow} y$, whence the class of such classes, when y is varied among the β's, is $\alpha \underset{,,}{\downarrow} ``\beta$, and

$$\beta \times \alpha = s`\alpha \underset{,,}{\downarrow} ``\beta \quad (\text{cf. } *40\cdot 7),$$

which we take as the definition of $\beta \times \alpha$.

We represent the arithmetical product of μ and ν by $\mu \times_c \nu$. This, as well as $\mathrm{Nc}`\alpha \times_c \mathrm{Nc}`\beta$, is defined in terms of $\alpha \times \beta$ exactly as, in $*110$, the sum was defined in terms of $\alpha + \beta$.

The present number contains many propositions which belong to the theory of $\alpha \underset{,,}{\downarrow} ``\beta$ rather than (specially) of $\beta \times \alpha$; and many propositions are rather logical than arithmetical in their nature, *i.e.* they might have been given in $*55$. The line is, however, so hard to draw that it has seemed better to deal simultaneously with all propositions on $\alpha \underset{,,}{\downarrow} ``\beta$ or on its sum, which is $\beta \times \alpha$. Thus in the present number, the early propositions, down to $*113\cdot 118$, deal mainly with logical properties of $\alpha \underset{,,}{\downarrow} ``\beta$ and $\beta \times \alpha$; the following propositions,

[*] We define this as $\beta \times \alpha$, rather than $\alpha \times \beta$, for the sake of certain analogies with products in relation-arithmetic. Cf. $*166$.

down to $*113{\cdot}13$, deal mainly with arithmetical properties of $\alpha \underset{\text{,,}}{\downarrow} \text{``}\beta$; the propositions $*113{\cdot}14$—$\cdot191$ are concerned mainly with arithmetical properties of $\beta \times \alpha$; $*113{\cdot}2$—$\cdot27$ deal with the simpler properties of $\mu \times_c \nu$; $*113{\cdot}3$—$\cdot34$ give propositions involving the multiplicative axiom, and exhibiting the connection (assuming this axiom) of addition and multiplication; $*113{\cdot}4$—$\cdot491$ are concerned with various forms of the distributive law; $*113{\cdot}5$—$\cdot541$ deal with the associative law of multiplication, and the remaining propositions deal with multiplication by 0 or 1 or 2.

The most important propositions in the present number are the following:

$*113{\cdot}101$. $\vdash : R \in \beta \times \alpha \,.\equiv .\, (\exists x, y) \,.\, x \in \alpha \,.\, y \in \beta \,.\, R = x \downarrow y$

This merely embodies the definition of $\beta \times \alpha$.

$*113{\cdot}105$. $\vdash : \exists ! \alpha \,.\supset .\, \alpha \underset{\text{,,}}{\downarrow} \in 1 \rightarrow 1$

This proposition is especially useful in dealing with exponentiation ($*116$).

$*113{\cdot}114$. $\vdash :.\, \alpha = \Lambda \,.\vee .\, \beta = \Lambda : \equiv .\, \beta \times \alpha = \Lambda$

It is in virtue of this proposition that a product of a finite number of factors only vanishes when one of its factors vanishes.

$*113{\cdot}118$. $\vdash .\, s\text{`}D\text{``}(\beta \times \alpha) \subset \alpha \,.\, s\text{`}\text{Ɑ}\text{``}(\beta \times \alpha) \subset \beta$

This proposition is chiefly useful in the analogous theory of ordinal products ($*165$, $*166$), where it enables us to apply $*74{\cdot}773$. Unless $\beta = \Lambda$, we have $s\text{`}D\text{``}(\beta \times \alpha) = \alpha$, and unless $\alpha = \Lambda$, $s\text{`}\text{Ɑ}\text{``}(\beta \times \alpha) = \beta$ ($*113{\cdot}116$).

$*113{\cdot}12$. $\vdash : \exists ! \alpha \,.\supset .\, \alpha \underset{\text{,,}}{\downarrow} \text{``}\beta \in \text{Nc}\text{`}\beta \cap \text{Cl excl}\text{`}\text{Nc}\text{`}\alpha$

I.e. unless α is null, $\alpha \underset{\text{,,}}{\downarrow} \text{``}\beta$ consists of $\text{Nc}\text{`}\beta$ mutually exclusive classes each having $\text{Nc}\text{`}\alpha$ members.

$*113{\cdot}127$. $\vdash : R \upharpoonright \gamma \in \alpha \,\overline{\text{sm}}\, \gamma \,.\, S \upharpoonright \delta \in \beta \,\overline{\text{sm}}\, \delta \,.\supset .$

$$(R \parallel \breve{S}) \upharpoonright (\delta \times \gamma) \in (\alpha \underset{\text{,,}}{\downarrow} \text{``}\beta) \,\overline{\text{sm}}\, \overline{\text{sm}}\, (\gamma \underset{\text{,,}}{\downarrow} \text{``}\delta)$$

This is an important proposition, since it gives a double correlator of $\alpha \underset{\text{,,}}{\downarrow} \text{``}\beta$ with $\gamma \underset{\text{,,}}{\downarrow} \text{``}\delta$ whenever simple correlators of α with γ and of β with δ are given. It leads at once to

$*113{\cdot}13$. $\vdash : \alpha \,\text{sm}\, \gamma \,.\, \beta \,\text{sm}\, \delta \,.\supset .\, \alpha \underset{\text{,,}}{\downarrow} \text{``}\beta \,\text{sm sm}\, \gamma \underset{\text{,,}}{\downarrow} \text{``}\delta \,.\, (\beta \times \alpha) \,\text{sm}\, (\delta \times \gamma)$

This proposition is fundamental in the theory of multiplication, since it shows that the number of members of $\beta \times \alpha$ depends only upon the numbers of members of α and β. It is also fundamental in the theory of exponentiation, as will appear in $*116$.

$*113{\cdot}141$. $\vdash .\, \text{Nc}\text{`}(\alpha \times \beta) = \text{Nc}\text{`}(\beta \times \alpha)$

This is the source of the commutative law of multiplication ($*113{\cdot}27$).

$*113{\cdot}146$. $\vdash : \alpha \neq \beta \,.\supset .\, \alpha \times \beta \,\text{sm}\, \epsilon_{\Delta}\text{`}(\iota\text{`}\alpha \cup \iota\text{`}\beta)$

This connects our present theory of multiplication with the theory of selections.

We come next to propositions concerning $\mu \times_0 \nu$. We have

***113·204.** $\vdash :. \mu = \Lambda . \mathbf{v} . \nu = \Lambda . \mathbf{v} . \sim(\mu, \nu \, \epsilon \, \text{NC}) : \supset . \mu \times_0 \nu = \Lambda$

The use of this proposition, like that of *110·4, is for avoiding trivial exceptions.

***113·23.** $\vdash . \mu \times_0 \nu \, \epsilon \, \text{NC}$

***113·25.** $\vdash . \text{Nc}`\gamma \times_0 \text{Nc}`\delta = \text{Nc}`(\gamma \times \delta)$

This proposition enables us to infer propositions on products of cardinals from propositions on products of classes, and is therefore constantly used.

***113·27.** $\vdash . \mu \times_0 \nu = \nu \times_0 \mu$

This is the commutative law of cardinal multiplication.

The chief proposition using the multiplicative axiom is

***113·31.** $\vdash :. \text{Mult ax} . \supset : \mu, \nu \, \epsilon \, \text{NC} . \kappa \, \epsilon \, \nu \cap \text{Cl}`\mu . \supset . \Sigma`\kappa \, \epsilon \, \mu \times_0 \nu$

I.e. assuming the multiplicative axiom, the sum of the numbers of members in ν classes of μ terms is $\mu \times_0 \nu$. If we had taken this sum as *defining* $\mu \times_0 \nu$, almost all propositions on multiplication would have required the multiplicative axiom. The advantage of $\alpha \underset{\prime\prime}{\downarrow} ``\beta$ is that, given $\alpha \text{ sm } \gamma$ and $\beta \text{ sm } \delta$, we can construct a double correlator of $\alpha \underset{\prime\prime}{\downarrow} ``\beta$ with $\gamma \underset{\prime\prime}{\downarrow} ``\delta$, without using the multiplicative axiom. This is proved in *113·127 (mentioned above).

The distributive law, which is next considered, has various forms. We have, to begin with,

***113·4.** $\vdash . (\beta \cup \gamma) \times \alpha = (\beta \times \alpha) \cup (\gamma \times \alpha)$

whence, using also the commutative law, we easily deduce

***113·43.** $\vdash . (\nu +_0 \varpi) \times_0 \mu = \mu \times_0 (\nu +_0 \varpi) = (\mu \times_0 \nu) +_0 (\mu \times_0 \varpi)$

But the distributive law also holds when, instead of enumerated summands β, γ or ν, ϖ, the summands are given as the members of a class κ, which may be infinite. We have

***113·48.** $\vdash . s`\alpha \times ``\kappa = \alpha \times s`\kappa = \text{Cnv}``\{(s`\kappa) \times \alpha\}$

whence, using the definitions of *112, we find

***113·491.** $\vdash : \kappa \, \epsilon \, \text{Cls}^2 \text{ excl} . \supset . \Sigma\text{Nc}`\alpha \times ``\kappa = \text{Nc}`(\alpha \times \Sigma`\kappa) = \text{Nc}`\alpha \times_0 \Sigma\text{Nc}`\kappa$

This is an extension of the distributive law to the case where the number of summands may be infinite.

The associative law

***113·54.** $\vdash . (\mu \times_0 \nu) \times_0 \varpi = \mu \times_0 (\nu \times_0 \varpi)$

is proved without any difficulty.

We prove next that $\mu \times_0 \nu = 0$ when, and only when, $\mu = 0$ or $\nu = 0$, μ, ν being existent cardinals (*113·602); that a cardinal is unchanged when it is multiplied by 1 (*113·62·621); that $\mu \times_0 2 = \mu +_0 \mu$ (*113·66) and that $\mu \times_0 (\nu +_0 1) = (\mu \times_0 \nu) +_0 \mu$ (*113·671).

***113·02.** $\beta \times \alpha = s‘\alpha \underset{,,}{\downarrow} “\beta$ Df

***113·03.** $\mu \times_0 \nu = \hat{\xi}\{(\exists \alpha, \beta) . \mu = \mathrm{N_0c}‘\alpha . \nu = \mathrm{N_0c}‘\beta . \xi \,\mathrm{sm}\, (\alpha \times \beta)\}$ Df

***113·04.** $\mathrm{Nc}‘\beta \times_0 \mu = \mathrm{N_0c}‘\beta \times_0 \mu$ Df

***113·05.** $\mu \times_0 \mathrm{Nc}‘\alpha = \mu \times_0 \mathrm{N_0c}‘\alpha$ Df

In relation to types, *113·03·04·05 call for similar remarks to those made in *110 for addition.

$\mu \times_0 \nu = \text{sm}_\eta``\mu \times_0 \text{sm}_\zeta``\nu$ (4)

$\vdash . (4) . *11·11·35·45 . (1) . \supset \vdash . \text{Prop}$

***113·261.** $\vdash : \mu, \nu \in \text{NC} . \supset . \mu \times_0 \nu = \mu^{(1)} \times_0 \nu^{(1)} = \mu_{(00)} \times_0 \nu_{(00)} = \text{etc.}$

Here "etc." includes all *ascending* derivatives of μ. We shall only prove the result for $\mu^{(1)}$ and $\nu^{(1)}$, since it is proved in just the same way for the other cases. $\mu^{(1)} \times_0 \nu^{(2)}$ or $\mu^{(1)} \times_0 \nu_{(00)}$ or etc. will serve equally well; *i.e.* it is not necessary to take the same derivative of μ as of ν.

Dem.

$\vdash . *104·264·265 . \supset$

$\vdash : \text{Hp} . \exists ! \mu . \exists ! \nu . \supset . \mu^{(1)} = \text{sm}_\mu``\mu . \nu^{(1)} = \text{sm}_\nu``\mu . \exists ! \mu^{(1)} . \exists ! \nu^{(1)} .$

$[*113·26] \qquad \supset . \mu \times_0 \nu = \mu^{(1)} \times_0 \nu^{(1)}$ (1)

$\vdash . *104·264 . *113·204 . \supset$

$\vdash : \sim(\exists ! \mu . \exists ! \nu) . \supset . \mu \times_0 \nu = \Lambda . \mu^{(1)} \times_0 \nu^{(1)} = \Lambda$ (2)

$\vdash . (1) . (2) . \supset \vdash . \text{Prop}$

As appears in the above proof, if μ^i and ν^j are any derivatives of μ and ν, the above proposition holds provided we have

$$\exists ! \mu . \exists ! \nu . \supset . \exists ! \mu^i . \exists ! \nu^j.$$

Thus it holds for all *ascending* derivatives, but not always for descending derivatives.

$\vdash . (2) . (3) . \supset \vdash . \mathrm{Prop}$

The following propositions are concerned with multiplication by a unit class or by 1 or 2.

***113·61.** $\vdash . \iota`z \times \alpha = \downarrow z``\alpha$

Dem.

$\vdash . *113·1 . \supset \vdash . \iota`z \times \alpha = s`\alpha \underset{''}{\downarrow} ``\iota`z$

[*53·31·02] $= \alpha \underset{''}{\downarrow} `z$

[*38·2] $= \downarrow z``\alpha . \supset \vdash . \mathrm{Prop}$

***113·611.** $\vdash . \iota`z \times \alpha \,\mathrm{sm}\, \alpha$ [*113·61 . *73·611]

***113·612.** $\vdash . \alpha \times \iota`z \,\mathrm{sm}\, \alpha$ [*113·611·141]

***113·62.** $\vdash . \mathrm{Nc}`\alpha \times_0 1 = \mathrm{Nc}`\alpha$

Dem.

$\vdash . *101·2 . \supset \vdash . \mathrm{Nc}`\alpha \times_0 1 = \mathrm{Nc}`\alpha \times_0 \mathrm{Nc}`\iota`z$

[*113·25] $= \mathrm{Nc}`(\alpha \times \iota`z)$

[*113·612] $= \mathrm{Nc}`\alpha . \supset \vdash . \mathrm{Prop}$

***113·621.** $\vdash : \mu \in \mathrm{NC} . \supset . \mu \times_0 1 = \mathrm{sm}``\mu$

Dem.

$\vdash . *113·204 . \supset \vdash : \mu = \Lambda . \supset . \mu \times_0 1 = \Lambda$

[*37·29] $= \mathrm{sm}``\mu$ (1)

$\vdash . *103·26 . \supset \vdash : \mathrm{Hp} . \alpha \in \mu . \supset . \mu = \mathrm{N_0c}`\alpha .$ (2)

[(*113·04)] $\supset . \mu \times_0 1 = \mathrm{Nc}`\alpha \times_0 1$

[*113·62] $= \mathrm{Nc}`\alpha$

[*103·4.(2)] $= \mathrm{sm}``\mu$ (3)

$\vdash . (2) . *10·11·23·35 . \supset \vdash : \mathrm{Hp} . \exists ! \mu . \supset . \mu \times_0 1 = \mathrm{sm}``\mu$ (4)

$\vdash . (1) . (4) . \supset \vdash . \mathrm{Prop}$

Observe that if μ is a typically definite cardinal, $\text{sm}``\mu$ is the "same" cardinal rendered typically ambiguous; while if $\mu$ is typically ambiguous, $\mu = \text{sm}``\mu$ in every type.

$*114$. THE ARITHMETICAL PRODUCT OF A CLASS OF CLASSES

Summary of $*114$.

The kind of multiplication defined in $*113$ cannot be extended beyond a finite number of factors. We therefore, as in the case of addition, introduce another definition, defining the product of the numbers of a class of classes, and capable of being applied to an infinite number of factors. We define the product of the numbers of members of κ as $\text{Nc}`\epsilon_\Delta`\kappa$; thus we put

$$\Pi\text{Nc}`\kappa = \text{Nc}`\epsilon_\Delta`\kappa \quad \text{Df.}$$

It is to be observed that $\Pi\text{Nc}`\kappa$ is not a function of $\text{Nc}``\kappa$, because, if two members of $\kappa$ have the same number, this will count only once in $\text{Nc}``\kappa$, but will count twice in $\Pi\text{Nc}`\kappa$.

It is very easy to see that, in case κ is finite, $\text{Nc}`\epsilon_\Delta`\kappa$ will be what we should ordinarily regard as the product of the numbers of members of κ. For suppose (*e.g.*)

$$\kappa = \iota`\alpha \cup \iota`\beta \cup \iota`\gamma,$$

where $\alpha \neq \beta \,.\, \alpha \neq \gamma \,.\, \beta \neq \gamma$. Then

$$\epsilon_\Delta`\kappa = \hat{R}\{(\exists x, y, z) \,.\, R = x \downarrow \alpha \,\dot{\cup}\, y \downarrow \beta \,\dot{\cup}\, z \downarrow \gamma \,.\, x \in \alpha \,.\, y \in \beta \,.\, z \in \gamma\}.$$

Thus if R is a member of $\epsilon_\Delta`\kappa$, R is determinate when x, y, z are given, x, y, z being the referents to α, β, γ. Whether α, β, γ overlap or not, the choice of any one of x, y, z is entirely independent of the choice of the other two, and therefore the total number of choices possible is obviously the product of the numbers of α, β, γ. Thus our definition will not conflict with what is commonly understood by a product.

The propositions of this number are less numerous and less important than those of $*113$. We shall deal first with products of a single factor, and products in which one factor is null ($*114{\cdot}2$—$\cdot27$). We shall then deal ($*114{\cdot}3$—$\cdot36$) with the relations between the sort of multiplication here defined and the sort defined in $*113$. Then we have a few propositions ($*114{\cdot}4$—$\cdot43$) showing that unit factors make no difference to the value of a product. Then we prove ($*114{\cdot}5$—$\cdot52$) that the value of the product is the same for two classes having double similarity, and then ($*114{\cdot}53$—$\cdot571$) we give extensions of this result which depend upon the multiplicative axiom. Finally, we give some new forms of the associative law of multiplication.

Among the more important propositions in this number are the following:

$*114{\cdot}21$. $\vdash \,.\, \Pi\text{Nc}`\iota`\alpha = \text{Nc}`\alpha$

I.e. a product of one factor is equal to that factor.

***114·23.** $\vdash : \Lambda \in \kappa . \supset . \Pi\text{Nc}`\kappa = 0$

I.e. a product vanishes if one of its factors is zero. The converse requires the multiplicative axiom, as appears from the proposition

***114·26.** $\vdash :. \text{Mult ax} . \equiv : \Pi\text{Nc}`\kappa = 0 . \equiv_\kappa . \Lambda \in \kappa$

I.e. the multiplicative axiom is equivalent to the assumption that a product vanishes when, and only when, one of its factors is zero.

***114·301.** $\vdash : \kappa \cap \lambda = \Lambda . \supset . \epsilon_\Delta`(\kappa \cup \lambda) \,\text{sm}\, \epsilon_\Delta`\kappa \times \epsilon_\Delta`\lambda$

whence

***114·31.** $\vdash : \kappa \cap \lambda = \Lambda . \supset . \Pi\text{Nc}`\kappa \times_c \Pi\text{Nc}`\lambda = \Pi\text{Nc}`(\kappa \cup \lambda)$

which is a form of the associative law, and

***114·35.** $\vdash : \alpha \neq \beta . \supset . \Pi\text{Nc}`(\iota`\alpha \cup \iota`\beta) = \text{Nc}`\alpha \times_c \text{Nc}`\beta$

which connects the two sorts of multiplication.

***114·41.** $\vdash : \lambda \subset 1 . \supset . \Pi\text{Nc}`(\kappa \cup \lambda) = \Pi\text{Nc}`\kappa$

I.e. unit factors make no difference to the value of a product.

***114·51.** $\vdash : T \upharpoonright s`\lambda \in \kappa \,\overline{\text{sm}}\,\overline{\text{sm}}\, \lambda . \supset . (T \| \breve{T}_\epsilon) \upharpoonright \epsilon_\Delta`\lambda \in (\epsilon_\Delta`\kappa) \,\overline{\text{sm}}\, (\epsilon_\Delta`\lambda)$

This proposition gives a correlator of $\epsilon_\Delta`\kappa$ and $\epsilon_\Delta`\lambda$ as a function of a double correlator of κ and λ, and thus leads to

***114·52.** $\vdash : \kappa \,\text{sm sm}\, \lambda . \supset . \Pi\text{Nc}`\kappa = \Pi\text{Nc}`\lambda . \epsilon_\Delta`\kappa \,\text{sm}\, \epsilon_\Delta`\lambda$

Hence, by the propositions of *111, we infer

***114·571.** $\vdash :. \text{Mult ax} . \supset : \mu, \nu \in \text{NC} . \kappa, \lambda \in \mu \cap \text{Cl}`\nu . \supset . \Pi\text{Nc}`\kappa = \Pi\text{Nc}`\lambda$

I.e. assuming the multiplicative axiom, if κ and λ each consist of μ classes of ν terms each, their products are equal.

We have next various forms of the associative law, beginning with

***114·6.** $\vdash : \kappa \in \text{Cls}^2 \,\text{excl} . \supset . \Pi\text{Nc}`\epsilon_\Delta``\kappa = \Pi\text{Nc}`s`\kappa$

which is an immediate consequence of *85·44. The other form is

***114·632.** $\vdash : S \upharpoonright \gamma \in 1 \rightarrow 1 . \gamma \subset \text{G}`S . \gamma \cap S``\gamma = \Lambda . \supset .$
$$\epsilon_\Delta`\hat{\mu}\{(\exists \alpha) . \alpha \in \gamma . \mu = \alpha \times S`\alpha\} \,\text{sm}\, \epsilon_\Delta`(\gamma \cup S``\gamma)$$

As to the sense in which this is a form of the associative law, see the observations following *114·6.

***114·01.** $\Pi\text{Nc}`\kappa = \text{Nc}`\epsilon_\Delta`\kappa$ Df

***114·1.** $\vdash . \Pi\text{Nc}`\kappa = \text{Nc}`\epsilon_\Delta`\kappa$ [(*114·01)]

***114·11.** $\vdash : \beta \in \Pi\text{Nc}`\kappa . \equiv . \beta \,\text{sm}\, \epsilon_\Delta`\kappa . \equiv . \beta \in \text{Nc}`\epsilon_\Delta`\kappa$ [*114·1 . *100·31]

***114·12.** $\vdash . \epsilon_\Delta`\kappa \in \Pi\text{Nc}`\kappa$ [*100·3 . *114·1]

***114·2.** $\vdash . \Pi\text{Nc}`\Lambda = 1$ [*83·15 . *101·2]

Thus a product of no factors is 1. This is the source of $\mu^0 = 1$, as we shall see later.

***114·21.** $\vdash . \Pi Nc`\iota`\alpha = Nc`\alpha$ [*83·41]

***114·22.** $\vdash . \Pi Nc`\iota`\Lambda = 0$ [*114·21 . *101·1]

***114·23.** $\vdash : \Lambda \epsilon \kappa . \supset . \Pi Nc`\kappa = 0$ [*83·11 . *101·1]

Thus an arithmetical product is zero if any of its factors is zero. To prove the converse, we have to assumé the multiplicative axiom, which, in fact, is equivalent to the proposition that an arithmetical product is only zero when at least one of its factors is zero.

***114·24.** $\vdash : \Pi Nc`\lambda \neq 0 . \kappa \subset \lambda . \supset . \Pi Nc`\kappa \neq 0$

Dem.

$\vdash . *114·1 . *101·1 . \supset \vdash : \Pi Nc`\lambda \neq 0 . \supset . \exists ! \epsilon_\Delta`\lambda$ (1)

This is the most general form of the associative law for arithmetical multiplication.

Owing to the fact that we have two kinds of multiplication, namely $\alpha \times \beta$ and $\epsilon_\Delta‘\kappa$, we have four forms of the associative law of multiplication, namely:

(1) *114·6, above,

(2) *113·54, *i.e.* $\vdash . (\mu \times_c \nu) \times_c \varpi = \mu \times_c (\nu \times_c \varpi)$,

(3) *114·31, *i.e.* $\vdash : \kappa \cap \lambda = \Lambda . \supset . \Pi\mathrm{Nc}‘\kappa \times_c \Pi\mathrm{Nc}‘\lambda = \Pi\mathrm{Nc}‘(\kappa \cup \lambda)$,

(4) a form of the associative law which has not yet been proved, which may be explained as follows.

Suppose we have a number of pairs of classes, *e.g.* (α_1, β_1), (α_2, β_2), (α_3, β_3), ... Suppose we form the products $\alpha_1 \times \beta_1$, $\alpha_2 \times \beta_2$, $\alpha_3 \times \beta_3, \ldots$ and multiply all these products together. We wish to prove that (with a suitable hypothesis) the result is similar to the product of all the α's and all the β's taken together as one class; *i.e.* if we call λ the class of products $\alpha_1 \times \beta_1, \alpha_2 \times \beta_2, \alpha_3 \times \beta_3, \ldots$, and μ the class whose members are $\alpha_1, \alpha_2, \alpha_3, \ldots, \beta_1, \beta_2, \beta_3, \ldots$, we wish to prove

$$\Pi\mathrm{Nc}‘\lambda = \Pi\mathrm{Nc}‘\mu.$$

In order to express this proposition in symbols, let S be the correlator of the α's and β's, so that $\beta_\nu = S‘\alpha_\nu$. (The suffix ν will not be used further, since it implies that the number of α's and of β's is finite or denumerable.) Then our class of products of the form $\alpha \times \beta$ is

$$\hat{\mu}\{(\exists \alpha) . \alpha \in \gamma . \mu = \alpha \times S‘\alpha\},$$

where γ is the class of all the α's; and the product of this class of products is

$$\epsilon_\Delta\text{‘}\hat{\mu}\{(\exists\alpha) \,.\, \alpha\in\gamma \,.\, \mu=\alpha\times S\text{‘}\alpha\}.$$

On the other hand, the class of all the α's and β's is $\gamma\cup S\text{‘‘}\gamma$, and the product of this class is

$$\epsilon_\Delta\text{‘}(\gamma\cup S\text{‘‘}\gamma).$$

Thus what we have to prove (with a suitable hypothesis) is

$$\epsilon_\Delta\text{‘}\hat{\mu}\{(\exists\alpha) \,.\, \alpha\in\gamma \,.\, \mu=\alpha\times S\text{‘}\alpha\} \operatorname{sm} \epsilon_\Delta\text{‘}(\gamma\cup S\text{‘‘}\gamma).$$

The hypothesis required is

$$S\upharpoonright\gamma\in 1\to 1 \,.\, \gamma\subset\text{Q‘}S \,.\, \gamma\cap S\text{‘‘}\gamma=\Lambda.$$

A smaller hypothesis suffices, however, for a proposition which, in virtue of $*114{\cdot}301$, is closely allied to the above, namely

$$\epsilon_\Delta\text{‘}\gamma\times\epsilon_\Delta\text{‘}S\text{‘‘}\gamma \operatorname{sm} \epsilon_\Delta\text{‘}\hat{\mu}\{(\exists\alpha) \,.\, \alpha\in\gamma \,.\, \mu=\alpha\times S\text{‘}\alpha\}.$$

For this, a sufficient hypothesis is

$$S\upharpoonright\gamma\in 1\to 1 \,.\, \gamma\subset\text{Q‘}S.$$

Thus *e.g.* we may write I for S, and we find

$$\vdash \,.\, \epsilon_\Delta\text{‘}\gamma\times\epsilon_\Delta\text{‘}\gamma \operatorname{sm} \epsilon_\Delta\text{‘}\hat{\mu}\{(\exists\alpha) \,.\, \alpha\in\gamma \,.\, \mu=\alpha\times\alpha\}.$$

We shall now prove the above propositions. What follows, down to $*114{\cdot}621$, consists of lemmas.

For convenience, we write $S_\times\text{‘}\alpha$ for $\alpha\times S\text{‘}\alpha$ in the course of these lemmas; this notation is introduced in the hypotheses of the lemmas.

[*114·64·301]

$*115$. MULTIPLICATIVE CLASSES AND ARITHMETICAL CLASSES

Summary of $*115$.

Whenever κ is a class of mutually exclusive classes, $\epsilon_\Delta{}^\backprime\kappa$ is similar to $\mathrm{D}{}^{\backprime\backprime}\epsilon_\Delta{}^\backprime\kappa$; hence

$$\Pi\mathrm{Nc}{}^\backprime\kappa = \mathrm{Nc}{}^\backprime\mathrm{D}{}^{\backprime\backprime}\epsilon_\Delta{}^\backprime\kappa.$$

Now $\mathrm{D}{}^{\backprime\backprime}\epsilon_\Delta{}^\backprime\kappa$ is of the same type as κ; and when κ is a class of mutually exclusive classes, $\mathrm{D}{}^{\backprime\backprime}\epsilon_\Delta{}^\backprime\kappa$ consists of all classes formed by selecting one representative from each member of κ. It often happens that $\mathrm{D}{}^{\backprime\backprime}\epsilon_\Delta{}^\backprime\kappa$ is easier to deal with than $\epsilon_\Delta{}^\backprime\kappa$; hence when possible (*i.e.* when $\kappa \in \mathrm{Cls}^2\,\mathrm{excl}$), it is convenient to use $\mathrm{D}{}^{\backprime\backprime}\epsilon_\Delta{}^\backprime\kappa$, rather than $\epsilon_\Delta{}^\backprime\kappa$, as the standard member of $\Pi\mathrm{Nc}{}^\backprime\kappa$. We therefore put

$$\mathrm{Prod}{}^\backprime\kappa = \mathrm{D}{}^{\backprime\backprime}\epsilon_\Delta{}^\backprime\kappa \quad \mathrm{Df.}$$

We shall call $\mathrm{Prod}{}^\backprime\kappa$ the "multiplicative class" of κ.

The associative law,

$$\mathrm{Prod}{}^\backprime s{}^\backprime\kappa \;\mathrm{sm}\; \mathrm{Prod}{}^\backprime\mathrm{Prod}{}^{\backprime\backprime}\kappa,$$

requires not merely $\kappa \in \mathrm{Cls}^2\,\mathrm{excl}$, but also $s{}^\backprime\kappa \in \mathrm{Cls}^2\,\mathrm{excl}$. The combination of these two hypotheses gives a completely disjointed class of classes of classes, *i.e.* a class of classes of classes κ which can be obtained by dividing a given class ($s{}^\backprime s{}^\backprime\kappa$) into mutually exclusive portions, and then dividing each of those portions into mutually exclusive portions. For example, take a square (a class of points) and divide it by horizontal lines, and then divide each of the resulting rectangles by vertical lines; then the resulting rows of little rectangles form such a class, each row of rectangles being one member of the class. Such a class we call an "arithmetical" class, and denote by "Cls^3 arithm."

The present number is concerned with the properties of multiplicative classes and arithmetical classes. Some of these properties will be useful in dealing with exponentiation.

The present number begins with various propositions concerning $\mathrm{Prod}{}^\backprime\kappa$ which are merely repetitions of previous propositions of $*83$, $*84$, $*85$ or $*113$. Thus we have

$*115{\cdot}141$. $\vdash : \exists ! \,\mathrm{Prod}{}^\backprime\kappa \,.\supset .\, s{}^\backprime\mathrm{Prod}{}^\backprime\kappa = s{}^\backprime\kappa$ by $*83{\cdot}66$,

$*115{\cdot}142$. $\vdash .\, \mathrm{Prod}{}^\backprime\iota{}^\backprime\alpha = \iota{}^{\backprime\backprime}\alpha$ by $*83{\cdot}7$,

$*115{\cdot}143$. $\vdash .\, \mathrm{Prod}{}^\backprime\iota{}^{\backprime\backprime}\alpha = \iota{}^\backprime\alpha$ by $*83{\cdot}71$,

$*115{\cdot}16$. $\vdash .\, \kappa \in \mathrm{Cls}^2\,\mathrm{excl} \,.\supset .\, \mathrm{Prod}{}^\backprime\kappa \subset \mathrm{Nc}{}^\backprime\kappa$ by $*100{\cdot}64$,

and various other properties.

We then proceed to consider Cls^3 arithm. We prove

***115·22.** $\vdash :. \kappa \in \mathrm{Cls}^3 \text{arithm} . \supset : s``\kappa \in \mathrm{Cls}^2 \text{excl} : \alpha, \beta \in \kappa . \exists ! s`\alpha \cap s`\beta . \supset_{\alpha,\beta} . \alpha = \beta$

and *115·23 gives a similar proposition substituting "Prod" for s.

After a few more propositions on Cls^3 arithm, we proceed to the associative law for Prod (*115·34), *i.e.*

$$\vdash : \kappa \in \mathrm{Cls}^3 \text{arithm} . \supset . \text{Prod}`\text{Prod}``\kappa \text{ sm Prod}`s`\kappa.$$

(This proposition, *115·34, also states that, with the same hypothesis, $\text{Prod}`s`\kappa \text{ sm } \epsilon_\Delta`s`\kappa$.) Hence we have

***115·35.** $\vdash : \kappa \in \mathrm{Cls}^3 \text{arithm} . \supset . \text{Nc}`\text{Prod}`\text{Prod}``\kappa = \text{Nc}`\text{Prod}`s`\kappa = \Pi \text{Nc}`\text{Prod}``\kappa$
$$= \Pi \text{Nc}`\epsilon_\Delta``\kappa = \Pi \text{Nc}`s`\kappa$$

We have also

***115·42.** $\vdash : \kappa \in \mathrm{Cls}^3 \text{arithm} . \supset . \text{Prod}`\text{Prod}``\kappa = \text{D}```\text{Prod}`\epsilon_\Delta``\kappa = \text{D}```\text{D}``\epsilon_\Delta`\epsilon_\Delta``\kappa$

***115·44.** $\vdash : \kappa \in \mathrm{Cls}^3 \text{arithm} . \supset . \text{Prod}`s`\kappa = s``\text{Prod}`\text{Prod}``\kappa$

We have next to prove that if two classes of classes have double similarity, so have their multiplicative classes. The proof is simple, since the double correlator is the same as for the original classes, *i.e.*

***115·502.** $\vdash : T \upharpoonright s`\lambda \in \kappa \,\overline{\text{sm}}\,\overline{\text{sm}}\, \lambda . \supset . T \upharpoonright s`\text{Prod}`\lambda \in (\text{Prod}`\kappa) \,\overline{\text{sm}}\,\overline{\text{sm}}\, (\text{Prod}`\lambda)$

whence

***115·51.** $\vdash : \kappa \text{ sm sm } \lambda . \supset . \text{Prod}`\kappa \text{ sm sm Prod}`\lambda$

The number ends with some propositions which result from *114·64·65 and are analogous to them. One of these is used in the following number in proving $\mu^\varpi \times_c \nu^\varpi = (\mu \times_c \nu)^\varpi$, namely,

***115·6.** $\vdash : (R``\gamma) \mathbin{\rceil} R, S \upharpoonright \gamma \in 1 \to 1 . \gamma \subset \text{ᗡ}`R . \gamma \subset \text{ᗡ}`S . R``\gamma, S``\gamma \in \mathrm{Cls}^2 \text{excl} . \supset .$
$$\text{Prod}`R``\gamma \times \text{Prod}`S``\gamma \text{ sm } \epsilon_\Delta`\hat{\mu}\{(\exists z) . z \in \gamma . \mu = R`z \times S`z\}$$

The subject of this number will be useful in dealing with exponentiation, since we shall define μ^ν by means of $\text{Prod}`\alpha \underset{,,}{\downarrow} ``\beta$, where $\mu = \text{N}_0\text{c}`\alpha$ and $\nu = \text{N}_0\text{c}`\beta$.

***115·01.** $\text{Prod}`\kappa = \text{D}``\epsilon_\Delta`\kappa$ Df

***115·02.** $\mathrm{Cls}^3 \text{arithm} = \hat{\kappa}(\kappa, s`\kappa \in \mathrm{Cls}^2 \text{excl})$ Df

***115·1.** $\vdash . \text{Prod}`\kappa = \text{D}``\epsilon_\Delta`\kappa$ [(*115·01)]

***115·101.** $\vdash :. \alpha \in \kappa . \supset_\alpha . \varpi \cap \alpha \in 1 : \varpi \subset s`\kappa : \supset . \varpi \in \text{Prod}`\kappa$ [*84·411]

***115·11.** $\vdash :: \kappa \in \mathrm{Cls}^2 \text{excl} . \supset :. \varpi \in \text{Prod}`\kappa . \equiv : \alpha \in \kappa . \supset_\alpha . \varpi \cap \alpha \in 1 : \varpi \subset s`\kappa$ [*84·412]

Owing to this proposition, $\text{Prod}`\kappa$ can be treated without any reference to $\epsilon_\Delta`\kappa$ whenever $\kappa \in \mathrm{Cls}^2$ excl.

$*115\cdot12$. $\vdash : \kappa \in \text{Cls}^2 \text{excl} . \supset . \text{Prod}'\kappa \in \Pi\text{Nc}'\kappa . \text{Prod}'\kappa \text{ sm } \epsilon_\Delta{}'\kappa$ [$*84\cdot41$]

It is this proposition that makes the notation $\text{Prod}'\kappa$ appropriate for the multiplicative class.

$*115\cdot13$. $\vdash : \alpha \cap \beta = \Lambda . \supset . \text{Prod}'(\iota'\alpha \cup \iota'\beta) \text{ sm } (\alpha \times \beta)$ [$*113\cdot152$]

$\vdash :. \mathrm{Hp} . \supset : \alpha, \beta \in \kappa . \exists ! s\text{‘}\alpha \cap s\text{‘}\beta . \supset . \alpha = \beta .$ (2)

[∗30·37] $\supset . s\text{‘}\alpha = s\text{‘}\beta$ (3)

$\vdash . (2) . (3) . *84{\cdot}11 . \supset \vdash . \mathrm{Prop}$

Observe that, although "$s\text{‘‘}\kappa \in \mathrm{Cls}^2\,\mathrm{excl}$" follows from

$$\text{“}\alpha, \beta \in \kappa . \exists ! s\text{‘}\alpha \cap s\text{‘}\beta . \supset_{\alpha,\beta} . \alpha = \beta,\text{”}$$

the converse implication does not hold. If there were two different classes α and β having the same sum, we might have $\exists ! s\text{‘}\alpha \cap s\text{‘}\beta$, *i.e.* $\exists ! s\text{‘}\alpha$, without having $\alpha = \beta$, in spite of "$s\text{‘‘}\kappa \in \mathrm{Cls}^2\,\mathrm{excl}$." In proofs, less use can be made of "$s\text{‘‘}\kappa \in \mathrm{Cls}^2\,\mathrm{excl}$" than of "$\alpha, \beta \in \kappa . \exists ! s\text{‘}\alpha \cap s\text{‘}\beta . \supset_{\alpha,\beta} . \alpha = \beta$." If $\Lambda \sim\in \kappa$ or $\iota\text{‘}\Lambda \sim\in \kappa$, the latter implies $s \upharpoonright \kappa \in 1 \to 1$.

∗115·23. $\vdash :. \kappa \in \mathrm{Cls}^3\,\mathrm{arithm} . \supset :$

$\mathrm{Prod}\text{‘‘}\kappa \in \mathrm{Cls}^2\,\mathrm{excl} : \alpha, \beta \in \kappa . \exists ! \mathrm{Prod}\text{‘}\alpha \cap \mathrm{Prod}\text{‘}\beta . \supset_{\alpha,\beta} . \alpha = \beta$

Dem.

$\vdash . *83{\cdot}62 . \quad \supset \vdash : \varpi \in \mathrm{Prod}\text{‘}\alpha \cap \mathrm{Prod}\text{‘}\beta . \supset . \varpi \subset s\text{‘}\alpha \cap s\text{‘}\beta$ (1)

$\vdash . (3) . (4) . \supset \vdash :. \mathrm{Hp} . \supset : \alpha, \beta \in \kappa . \exists ! \mathrm{Prod}\text{‘}\alpha \cap \mathrm{Prod}\text{‘}\beta . \supset . \alpha = \beta .$ (5)

[∗30·37] $\supset . \mathrm{Prod}\text{‘}\alpha = \mathrm{Prod}\text{‘}\beta$ (6)

$\vdash . (5) . (6) . *84{\cdot}11 . \supset \vdash . \mathrm{Prop}$

∗115·24. $\vdash : \kappa \in \mathrm{Cls}^3\,\mathrm{arithm} . \equiv . \epsilon \upharpoonright \kappa, \epsilon \upharpoonright s\text{‘}\kappa \in \mathrm{Cls} \to 1$ [∗115·2 . ∗84·14]

∗115·25. $\vdash : \kappa \in \mathrm{Cls}^3\,\mathrm{arithm} . \supset . \epsilon_\Delta\text{‘}\kappa \subset 1 \to 1 . \epsilon_\Delta\text{‘}s\text{‘}\kappa \subset 1 \to 1$ [∗84·3 . ∗115·2]

***115·26.** $\vdash : \kappa \in \text{Cls}^3 \text{ arithm} . \supset .$

$$\epsilon_\Delta{}^\text{‘}s^\text{‘‘}\kappa \subset 1 \to 1 . \epsilon_\Delta{}^\text{‘}\epsilon_\Delta{}^\text{‘‘}\kappa \subset 1 \to 1 . \epsilon_\Delta{}^\text{‘}\text{Prod}^\text{‘‘}\kappa \subset 1 \to 1$$

[*84·3 . *115·22 . *84·55 . *115·23]

In the above proposition, $\epsilon_\Delta{}^\text{‘}\epsilon_\Delta{}^\text{‘‘}\kappa \subset 1 \to 1$ does not require the hypothesis $\kappa \in \text{Cls}^3$ arithm, being true always. It is merely included here for convenience of reference.

***115·27.** $\vdash : \kappa \in \text{Cls}^3 \text{ arithm} . \supset . \kappa \subset \text{Cls}^2 \text{ excl}$ [*115·2 . *84·25 . *40·13]

We have now to prove the associative law for "Prod," *i.e.*

$$\kappa \in \text{Cls}^3 \text{ arithm} . \supset . \text{Prod}^\text{‘}s^\text{‘}\kappa \text{ sm Prod}^\text{‘}\text{Prod}^\text{‘‘}\kappa.$$

In virtue of *115·12, we have only to prove (under the hypothesis)

$$\epsilon_\Delta{}^\text{‘}s^\text{‘}\kappa \text{ sm } \epsilon_\Delta{}^\text{‘}\text{Prod}^\text{‘‘}\kappa$$

which, by *85·44, will follow from

$$\epsilon_\Delta{}^\text{‘}\epsilon_\Delta{}^\text{‘‘}\kappa \text{ sm } \epsilon_\Delta{}^\text{‘}\text{Prod}^\text{‘‘}\kappa$$

which, by *114·52, will follow from

$$\epsilon_\Delta{}^\text{‘‘}\kappa \text{ sm sm Prod}^\text{‘‘}\kappa.$$

Now $\qquad \text{Prod}^\text{‘‘}\kappa = \text{D}_\epsilon{}^\text{‘‘}\epsilon_\Delta{}^\text{‘‘}\kappa.$

Thus the correlator which will give our proposition will be $\text{D} \upharpoonright s^\text{‘}\epsilon_\Delta{}^\text{‘‘}\kappa$. We have only to prove that this is a $1 \to 1$, and the rest follows.

***115·3.** $\vdash : \kappa \in \text{Cls}^3 \text{ arithm} . R, S \in s^\text{‘}\epsilon_\Delta{}^\text{‘‘}\kappa . \text{D}^\text{‘}R = \text{D}^\text{‘}S . \supset . R = S$

[*115·33·12·23]

This proposition gives the associative law for "Prod."

The following proposition embodies the last three propositions.

***115·35.** $\vdash : \kappa \in \text{Cls}^3\,\text{arithm} \,.\, \supset .$

$$\text{Nc}`\text{Prod}`\text{Prod}``\kappa = \text{Nc}`\text{Prod}`s`\kappa = \Pi\text{Nc}`\text{Prod}``\kappa = \Pi\text{Nc}`\epsilon_\Delta``\kappa = \Pi\text{Nc}`s`\kappa$$

[*115·34·33·32]

In connection with $\text{Prod}`s`\kappa$ and $\text{Prod}`\text{Prod}``\kappa$, there remain two propositions of sufficient interest to deserve proof, namely

$$\kappa \in \text{Cls}^3\,\text{arithm} \,.\, \supset .\, \text{Prod}`s`\kappa = s``\text{Prod}`\text{Prod}``\kappa$$

and

$$\kappa \in \text{Cls}^3\,\text{arithm} \,.\, \supset .\, \text{Prod}`\text{Prod}``\kappa = \text{D}```\text{D}``\epsilon_\Delta`\epsilon_\Delta``\kappa.$$

Of these, the first is deduced from the second, while the second is proved by means of *114·51, putting D for the T which appears in that proposition, and $\epsilon_\Delta``\kappa$ for the λ of that proposition.

***115·4.** $\vdash : T \upharpoonright s`\lambda \in 1 \to 1 \,.\, s`\lambda \subset \text{Ɑ}`T \,.\, \supset .\, \text{Prod}`T```\lambda = T```\text{Prod}`\lambda$

$*116$. EXPONENTIATION

Summary of $*116$.

In this number, we define "$\alpha \exp \beta$," meaning "α to the exponent β," where α and β are classes, as

$$\text{Prod}`\alpha \underset{,,}{\downarrow} ``\beta.$$

Now $\text{Prod}`\alpha \underset{,,}{\downarrow} ``\beta$ consists of all ways of selecting one each from the members of $\alpha \underset{,,}{\downarrow} ``\beta$, *i.e.* from the classes $\downarrow y``\alpha$, where $y \in \beta$. Thus to get a member of $\text{Prod}`\alpha \underset{,,}{\downarrow} ``\beta$, take a set of couples $x \downarrow y$, where x is always an α, and there is only one x for a given y, and y is each member of β in succession. Thus for each member of β, we have $\text{Nc}`\alpha$ possible referents; hence it is plain that the number of possible sets of couples consists of $\text{Nc}`\beta$ factors each equal to $\text{Nc}`\alpha$, and is therefore fit to be taken as defining $(\text{Nc}`\alpha)^{\text{Nc}`\beta}$.

The definitions of μ^ν and $(\text{Nc}`\alpha)^{\text{Nc}`\beta}$ are derived from the definition of $\alpha \exp \beta$ exactly as the definitions of $\mu +_c \nu$ and $\text{Nc}`\alpha +_c \text{Nc}`\beta$, or of $\mu \times_c \nu$ and $\text{Nc}`\alpha \times_c \text{Nc}`\beta$, were derived respectively from $\alpha + \beta$ and $\alpha \times \beta$.

The chief difficulty in this number lies in the proof of the three formal laws of exponentiation, namely

$$\mu^\nu \times_c \mu^\varpi = \mu^{\nu +_c \varpi},$$

$$\mu^\varpi \times_c \nu^\varpi = (\mu \times_c \nu)^\varpi,$$

and

$$(\mu^\nu)^\varpi = \mu^{\nu \times_c \varpi}.$$

The proofs of the second and third of these, in particular, require various lemmas; but there is no difficulty involved except the complexity of the classes and relations concerned.

The definition of μ^ν is so framed as to minimize the necessity for the multiplicative axiom (see the note on $*113\cdot31$ in the introduction to $*113$). We have

$*116\cdot36$. $\vdash :. \text{Mult ax} . \supset : \mu, \nu \in \text{NC} - \iota`\Lambda . \kappa \in \nu \cap \text{Cl}`\mu . \supset . \Pi\text{Nc}`\kappa = \mu^\nu$

that is, assuming the multiplicative axiom, the product of ν factors each equal to μ is μ^ν (assuming μ and ν to be cardinals which are not null). If we had *defined* μ^ν as the product of ν factors each equal to μ, we should have required the multiplicative axiom for almost all propositions on μ^ν; but by taking the particular class $\alpha \underset{,,}{\downarrow} ``\beta$, we avoid the multiplicative axiom except in a few propositions. Among these few is the above proposition connecting exponentiation with multiplication.

Cantor has defined μ^ν by means of the class of "Belegungen," *i.e.* the class

$$\hat{R}(R \in 1 \to \text{Cls} . \text{D}`R \subset \alpha . \text{Ͻ}`R = \beta)$$

which (*116·12) $= (\alpha \uparrow \beta)_\Delta{}^\backprime\beta$. By *85·53 and *113·103, this class is equal to $\dot{s}^{\backprime\backprime}(\alpha \exp \beta)$ (as is proved in *116·13), whence, since $\dot{s} \upharpoonright \alpha \exp \beta \epsilon 1 \rightarrow 1$, it follows (*116·15) that the class of "Belegungen" is similar to $\alpha \exp \beta$. Hence our definition gives the same value of μ^ν as Cantor's.

The propositions of the present number begin with various simple properties of $\alpha \exp \beta$. Its existence follows from

***116·152.** $\vdash : x \epsilon \alpha . \supset . x \downarrow {}^{\backprime\backprime}\beta \epsilon (\alpha \exp \beta)$

whence (*116·16) $\vdash . \mathrm{Cnv}^{\backprime\backprime\backprime}\beta \underset{,,}{\downarrow} {}^{\backprime\backprime}\alpha \subset \alpha \exp \beta$, and

***116·18.** $\vdash :. \exists ! \alpha . \mathrm{v} . \beta = \Lambda : \equiv . \exists ! \alpha \exp \beta$

We have

***116·19.** $\vdash : \alpha \,\mathrm{sm}\, \gamma . \beta \,\mathrm{sm}\, \delta . \supset . (\alpha \exp \beta) \,\mathrm{sm}\,\mathrm{sm}\, (\gamma \exp \delta)$

in virtue of *113·13 and *115·51. *116·192 shows that, if $R \upharpoonright \gamma$ correlates α with γ, and $S \upharpoonright \delta$ correlates β with δ, then $(R \,\|\, \breve{S}) \upharpoonright (\delta \times \gamma)$ is a double correlator of $(\alpha \exp \beta)$ with $(\gamma \exp \delta)$.

We then proceed to a set of propositions on μ^ν, which are analogous to *113·2 ff. on $\mu \times_0 \nu$. We have

***116·203.** $\vdash : \exists ! \mu^\nu . \supset . \mu, \nu \epsilon \mathrm{NC} - \iota^\backprime\Lambda . \mu, \nu \epsilon \mathrm{N_0C}$

***116·25.** $\vdash . (\mathrm{Nc}^\backprime\gamma)^{\mathrm{Nc}^\backprime\delta} = \mathrm{Nc}^\backprime(\gamma \exp \delta)$

and various other less useful propositions.

We then have various propositions on 0 and 1 and 2. We prove

***116·301.** $\vdash : \mu \epsilon \mathrm{NC} - \iota^\backprime\Lambda . \supset . \mu^0 = 1$

***116·311.** $\vdash : \nu \epsilon \mathrm{NC} - \iota^\backprime\Lambda - \iota^\backprime 0 . \supset . 0^\nu = 0$

***116·321.** $\vdash : \mu \epsilon \mathrm{NC} - \iota^\backprime\Lambda . \supset . \mu^1 = \mathrm{sm}^{\backprime\backprime}\mu$

(Observe that $\mathrm{sm}^{\backprime\backprime}\mu$ is the same cardinal as μ, but rendered typically ambiguous.)

***116·331.** $\vdash : \mu \epsilon \mathrm{NC} - \iota^\backprime\Lambda . \supset . 1^\mu = 1$

***116·34.** $\vdash . \mu^2 = \mu \times_0 \mu$

(This proposition does not require that μ should be a cardinal.)

After the proposition (*116·36) already quoted, on the connection of exponentiation and multiplication, we proceed to a set of propositions on the case where a number of classes are all given as similar (by assignable correlations) to a given class. In *116·411, we prove that if κ is a class of mutually exclusive classes, each of which is similar to a given class γ, and if, when $\alpha \epsilon \kappa$, $M^\backprime\alpha$ is a correlator of α and γ, and T is the sum of $M^{\backprime\backprime}\kappa$, then

$$\mathrm{Nc}^\backprime\epsilon_\Delta{}^\backprime\overrightarrow{T}^{\backprime\backprime}\gamma = \mathrm{Nc}^\backprime T_\Delta{}^\backprime\gamma = \mathrm{Nc}^\backprime(\kappa \exp \gamma) = (\mathrm{Nc}^\backprime\kappa)^{\mathrm{Nc}^\backprime\gamma}.$$

This is a further connection of multiplication and exponentiation. (On the purport of this and following propositions, see the explanation preceding $*116{\cdot}4$.) In $*116{\cdot}43$, the hypothesis is somewhat modified. We still have a set κ of classes which are all similar to γ, but the correlator for a given class α is not given as $M`\alpha$, but is given as $M`w$, where w is a member of a class δ which is similar to κ. Then $\kappa = \text{D}``M``\delta$. We assume that $M \upharpoonright \delta$ is a one-one, and that if $M`w$ and $M`v$ have domains which overlap, then $w = v$. Thus κ is a class of mutually exclusive classes, each of which has $\text{Nc}`\gamma$ terms, while $\kappa$ has $\text{Nc}`\delta$ terms. Then it is proved in $*116{\cdot}43$ that

$$\text{Prod}`\text{D}``M``\delta \text{ sm sm } (\gamma \exp \delta) \,.\, \Pi\text{Nc}`\text{D}``M``\delta = (\text{Nc}`\gamma)^{\text{Nc}`\delta}.$$

This proposition and another ($*116{\cdot}45$) which follows from it are useful in proving the formal laws of exponentiation. The proof of these occupies the following propositions from $*116{\cdot}5$ to $*116{\cdot}68$. We have

$*116{\cdot}52$. $\vdash \,.\, \mu^{\nu} \times_0 \mu^{\varpi} = \mu^{\nu +_c \varpi}$

$*116{\cdot}55$. $\vdash \,.\, \mu^{\varpi} \times_0 \nu^{\varpi} = (\mu \times_0 \nu)^{\varpi}$

$*116{\cdot}63$. $\vdash \,.\, \mu^{\nu \times_0 \varpi} = (\mu^{\nu})^{\varpi}$

An extension of the first of these is

$*116{\cdot}661$. $\vdash \,.\, \Pi\text{Nc}`(\alpha \exp)``\kappa = (\text{Nc}`\alpha)^{\Sigma\text{Nc}`\kappa}$

Here the number of members of κ need not be finite. The purport of the proposition is as follows: Let $\beta, \gamma, \delta, \ldots$ be the members of κ; form $\alpha \exp \beta$, $\alpha \exp \gamma$, $\alpha \exp \delta$, $\ldots$, and take the product of the numbers of all these; then the resulting number is the same as if we first took the sum of the numbers of all the members of κ, thus obtaining (say) a number μ, and raised $\text{Nc}`\alpha$ to the μth power.

An extension of $*116{\cdot}55$ is given by $*116{\cdot}68$, where we prove

$$\vdash : \kappa \in \text{Cls}^2 \text{ excl} \,.\, \supset \,.\, \Pi\text{Nc}`\exp \gamma``\kappa = (\Pi\text{Nc}`\kappa)^{\text{Nc}`\gamma}.$$

There is no analogous extension of $*116{\cdot}63$.

We prove next Cantor's proposition (which is very useful)

$*116{\cdot}72$. $\vdash \,.\, \text{Nc}`\text{Cl}`\alpha = 2^{\text{Nc}`\alpha}$

I.e. the number of combinations of μ things any number at a time is 2^{μ}. (Observe that μ need not be finite.) The remainder of the number is concerned with consequences of this proposition.

$*116{\cdot}01$. $\alpha \exp \beta = \text{Prod}`\alpha \underset{;}{\downarrow} ``\beta$ Df

$*116{\cdot}02$. $\mu^{\nu} = \hat{\gamma}\{(\exists \alpha, \beta) \,.\, \mu = \text{N}_0\text{c}`\alpha \,.\, \nu = \text{N}_0\text{c}`\beta \,.\, \gamma \text{ sm } (\alpha \exp \beta)\}$ Df

$*116{\cdot}03$. $(\text{Nc}`\alpha)^{\nu} = (\text{N}_0\text{c}`\alpha)^{\nu}$ Df

$*116{\cdot}04$. $\mu^{\text{Nc}`\beta} = \mu^{\text{N}_0\text{c}`\beta}$ Df

It would not be an error to write "$\mu^1 = \mu$" instead of "$\mu^1 = \text{sm}^{\prime\prime}\mu$" in the above proposition. For if the "sm" is typically determined so that $\text{sm}^{\prime\prime}\mu \in t'\mu$, then $\text{sm}^{\prime\prime}\mu = \mu$. Thus in virtue of *116·321, $\mu^1 = \mu$ is true whenever it is significant. But the above form gives more information, since it preserves the typical ambiguity of μ^1 and $\text{sm}^{\prime\prime}\mu$.

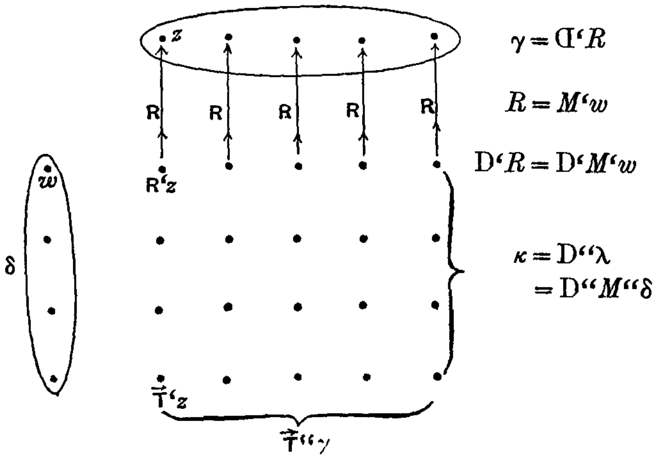
$\vdash . (1) . *116{\cdot}36 . \supset \vdash . \mathrm{Prop}$

The following propositions, which illustrate certain generalizations of the relations of rows and columns, may be made clearer by the accompanying



figure, in which, for the sake of simplicity, all the classes concerned are taken to be finite.

Let κ be a set of classes, constituted by four rows of five dots in the figure, which are each given as similar to a given class γ, represented by the top row of five dots in the figure, namely the row enclosed in an oval. We assume that an actual correlating relation is given correlating each member of κ with γ. Let λ be the class of these relations, and assume that λ consists of one correlator for each member of κ, and that $\kappa \in \mathrm{Cls}^2\,\mathrm{excl}$. Thus $\mathrm{D}``\lambda = \kappa$, and $R \in \lambda . \supset . \text{Ɑ}`R = \gamma$. Put $T = \breve{s}`\lambda$. Then, if $z \in \gamma$, T relates to z every member of the column below z, *i.e.* $\overrightarrow{T}`z$ consists of the four dots which are vertically below z; assuming, what in the circumstances is possible, that each dot is placed below its correlate in γ. Thus $\overrightarrow{T}``\gamma$ represents the columns, while $\mathrm{D}``\lambda$ represents the rows.

We prove, in *116·41, that $\overrightarrow{T}``\gamma$, the class of rows, has double similarity with $\lambda \underset{\prime\prime}{\downarrow} ``\gamma$, or, what comes to the same thing, with $\kappa \underset{\prime\prime}{\downarrow} ``\gamma$. Hence it follows that $T``\gamma$, which is the whole class of dots, is similar to $\gamma \times \lambda$ or $\gamma \times \kappa$, and that $\mathrm{Nc}`\epsilon_{\Delta}`\overrightarrow{T}``\gamma$, which is the product of the numbers of the columns, is equal

to $(\mathrm{Nc}\text{‘}\lambda)^{\mathrm{Nc}\text{‘}\gamma}$ or $(\mathrm{Nc}\text{‘}\kappa)^{\mathrm{Nc}\text{‘}\gamma}$. The correlator which is used for proving these propositions is W, where, if R is a member of λ and z is a member of γ, W correlates $R\text{‘}z$ with $R \downarrow z$.

Similarly, by correlating $R\text{‘}z$ with $z \downarrow R$, calling the correlator U, we have $U\text{‘‘} \downarrow R\text{‘‘}\gamma = R\text{‘‘}\gamma$, *i.e.* $U_\epsilon\text{‘}\gamma \underset{,,}{\downarrow} R = \mathrm{D}\text{‘}R$, whence $U_\epsilon\text{‘‘}\gamma \underset{,,}{\downarrow} \text{‘‘}\lambda = \mathrm{D}\text{‘‘}\lambda$. Hence $\mathrm{D}\text{‘‘}\lambda$, *i.e.* the class of rows, has double similarity with $\gamma \underset{,,}{\downarrow} \text{‘‘}\lambda$ or $\gamma \underset{,,}{\downarrow} \text{‘‘}\kappa$, whence the product of the numbers of the rows is $(\mathrm{Nc}\text{‘}\gamma)^{\mathrm{Nc}\text{‘}\lambda}$ or $(\mathrm{Nc}\text{‘}\gamma)^{\mathrm{Nc}\text{‘}\kappa}$.

Finally, we take a class δ similar to κ or λ (illustrated in the figure by the column of dots enclosed in an oval), and calling M a correlator of λ and δ, we replace λ by $M\text{‘‘}\delta$ and κ by $\mathrm{D}\text{‘‘}M\text{‘‘}\delta$. We thus find that, if $M \upharpoonright \delta$ correlates with δ a class of relations whose domains are mutually exclusive, and which each correlate their domains with a given class γ, then $\mathrm{D}\text{‘‘}M\text{‘‘}\delta$ has double similarity with $\gamma \underset{,,}{\downarrow} \text{‘‘}\delta$, whence the same results as before with δ in place of κ or λ.

The following propositions are useful in connecting multiplication with exponentiation, and in proving the formal laws of exponentiation.

$*116{\cdot}4{\cdot}401$ are lemmas for $*116{\cdot}41$.

The above proposition is used in $*116\cdot676$.

We have now to prove the three formal laws of exponentiation, namely

$$\mu^\nu \times_c \mu^\varpi = \mu^{\nu +_c \varpi},$$
$$\mu^\varpi \times_c \nu^\varpi = (\mu \times_c \nu)^\varpi,$$
and
$$(\mu^\nu)^\varpi = \mu^{\nu \times_c \varpi}.$$

Of these the first is an immediate consequence of the distributive law, while the second and third result from forms of the associative law of multiplication.

$\vdash . (2) . (3) . (6) . \supset \vdash . \text{Prop}$

The following propositions are lemmas for

$$\mu^\varpi \times_c \nu^\varpi = (\mu \times_c \nu)^\varpi .$$

The principal previous propositions used in the proof are $*115{\cdot}6$ and $*116{\cdot}43$. The proof proceeds as follows.

$(\alpha \exp \gamma) \times (\beta \exp \gamma)$ is $\text{Prod}\text{‘}\alpha\underset{,,}{\downarrow}\text{“}\gamma \times \text{Prod}\text{‘}\beta\underset{,,}{\downarrow}\text{“}\gamma$. This, using $*115\cdot6$, and putting $\alpha\underset{,,}{\downarrow}$, $\beta\underset{,,}{\downarrow}$ in place of R and S of that proposition, is similar to $\epsilon_\Delta\text{‘}\hat{\mu}\{(\exists z) . z \in \gamma . \mu = \alpha\underset{,,}{\downarrow} z \times \beta\underset{,,}{\downarrow} z\}$, *i.e.* to $\epsilon_\Delta\text{‘}\hat{\mu}\{(\exists z) . z \in \gamma . \mu = \downarrow z\text{“}\alpha \times \downarrow z\text{“}\beta\}$.

Now by $*113\cdot65$, putting $R\dagger = R \| \breve{R}$ Dft, $\downarrow z\text{“}\alpha \times \downarrow z\text{“}\beta = (\downarrow z)\dagger\text{“}(\alpha \times \beta)$. We now apply $*116\cdot43$, taking $(\downarrow z)\dagger$ as the $M\text{‘}z$ of that proposition, or rather, taking $(\downarrow z)\dagger \upharpoonright (\alpha \times \beta)$. Thus we find

$$\epsilon_\Delta\text{‘}\hat{\mu}\{(\exists z) . z \in \gamma . \mu = \downarrow z\text{“}\alpha \times \downarrow z\text{“}\beta\} \text{ sm } (\alpha \times \beta) \exp \gamma.$$

Hence our proposition follows.

$*116\cdot529$. $R\dagger = R \| \breve{R}$ Dft [$*116$]

In $*150$, this notation will be introduced as a permanent definition. For the present, we only introduce it to avoid $(\downarrow z \| \text{Cnv}\text{‘}\downarrow z)$, which is awkward.

$*116\cdot53$. $\vdash : \exists ! \alpha . \exists ! \beta . \supset .$

$$(\alpha \exp \gamma) \times (\beta \exp \gamma) \text{ sm } \epsilon_\Delta\text{‘}\hat{\mu}\{(\exists z) . z \in \gamma . \mu = \downarrow z\text{“}\alpha \times \downarrow z\text{“}\beta\}$$

Dem.

$\vdash . *113\cdot104\cdot111 . \supset \vdash . \gamma \subset \text{Ɑ}\text{‘}\alpha\underset{,,}{\downarrow} . \gamma \subset \text{Ɑ}\text{‘}\beta\underset{,,}{\downarrow} . \alpha\underset{,,}{\downarrow}\text{“}\gamma, \beta\underset{,,}{\downarrow}\text{“}\gamma \in \text{Cls}^2\text{excl}$ (1)

$\vdash . *113\cdot105 . \quad \supset \vdash : \text{Hp} . \supset . (\alpha\underset{,,}{\downarrow}\text{“}\gamma) \rceil \alpha\underset{,,}{\downarrow}, \beta\underset{,,}{\downarrow} \upharpoonright \gamma \in 1 \to 1$ (2)

$\vdash . (1) . (2) . *115\cdot6 \dfrac{\alpha\underset{,,}{\downarrow}, \beta\underset{,,}{\downarrow}}{R, \ S} . \supset$

$\vdash : \text{Hp} . \supset . (\alpha \exp \gamma) \times (\beta \exp \gamma) \text{ sm } \epsilon_\Delta\text{‘}\hat{\mu}\{(\exists z) . z \in \gamma . \mu = \alpha\underset{,,}{\downarrow} z \times \beta\underset{,,}{\downarrow} z\}$ (3)

$\vdash . (3) . *38\cdot2 . \supset \vdash . \text{Prop}$

The hypothesis $\exists ! \alpha . \exists ! \beta$ is not necessary in the above proposition; but the proof is simpler with the hypothesis, and we do not need the proposition without the hypothesis.

$*116\cdot531$. $\vdash :. M = \hat{R}\hat{z}\{z \in \gamma . R = (\downarrow z)\dagger \upharpoonright (\alpha \times \beta)\} . \supset :$

$*117$. GREATER AND LESS

Summary of $*117$.

A cardinal μ is said to be greater than another cardinal ν when there is a class α which has μ terms and has a part which has ν terms, while there is no class β which has ν terms and has a part which has μ terms. The relation "greater than" is transitive and asymmetrical; and by the Schröder-Bernstein theorem, if μ is greater than or equal to ν, and ν is greater than or equal to μ, then $\mu = \nu$. But we cannot prove that of any two cardinals one must be the greater, unless we assume the multiplicative axiom. The proof then follows from Zermelo's theorem that on that assumption every class can be well-ordered. This subject will be dealt with at a later stage.

The form of the definitions is so arranged as to allow of the inequality of two cardinals in different types. The relevant considerations are the same as for the definitions of addition, multiplication and exponentiation.

Our definition of "$\mu > \nu$" is

$*117\cdot01$. $\mu > \nu \,.=.\, (\exists \alpha, \beta) \,.\, \mu = \mathrm{N_0c}`\alpha \,.\, \nu = \mathrm{N_0c}`\beta \,.$
$\qquad\qquad \exists ! \,\mathrm{Cl}`\alpha \cap \mathrm{Nc}`\beta \,.\, \sim\exists ! \,\mathrm{Cl}`\beta \cap \mathrm{Nc}`\alpha$ Df

We also define "$\mu > \mathrm{Nc}`\alpha$" as meaning "$\mu > \mathrm{N_0c}`\alpha$," and "$\mathrm{Nc}`\alpha > \nu$" as meaning "$\mathrm{N_0c}`\alpha > \nu$," for the reasons explained in $*110$. It then easily follows that if $\mu > \nu$, μ and ν must be homogeneous cardinals (this is part of $*117\cdot15$); that if μ and ν are homogeneous cardinals, and $\mu > \nu$, the same holds if we substitute $\mathrm{sm}``\mu$ and $\mathrm{sm}``\nu$ for one or both of μ and ν ($*117\cdot16$); that

$*117\cdot13$. $\vdash : \mathrm{Nc}`\alpha > \mathrm{Nc}`\beta \,.\equiv.\, \exists ! \,\mathrm{Cl}`\alpha \cap \mathrm{Nc}`\beta \,.\, \sim\exists ! \,\mathrm{Cl}`\beta \cap \mathrm{Nc}`\alpha$

and that

$*117\cdot14$. $\vdash : \mu > \nu \,.\equiv.\, (\exists \alpha, \beta) \,.\, \mu = \mathrm{N_0c}`\alpha \,.\, \nu = \mathrm{N_0c}`\beta \,.\, \mathrm{Nc}`\alpha > \mathrm{Nc}`\beta$

We cannot define "$\mu \geqslant \nu$" as "$\mu > \nu \,.\vee.\, \mu = \nu$," because "$\mu = \nu$" restricts μ and ν too much by requiring that they should be of the same type, and restricts them too little by not requiring that they should both be existent cardinals. To avoid both these inconveniences, we put

$*117\cdot05$. $\mu \geqslant \nu \,.=:\, \mu > \nu \,.\vee.\, \mu, \nu \in \mathrm{N_0C} \,.\, \mu = \mathrm{sm}``\nu$ Df

The use of this definition is chiefly through the propositions

$*117\cdot108$. $\vdash :. \mathrm{Nc}`\alpha \geqslant \mathrm{Nc}`\beta \,.\equiv:\, \mathrm{Nc}`\alpha > \mathrm{Nc}`\beta \,.\vee.\, \mathrm{Nc}`\alpha = \mathrm{Nc}`\beta$

$*117\cdot24$. $\vdash : \mu \geqslant \nu \,.\equiv.\, (\exists \alpha, \beta) \,.\, \mu = \mathrm{N_0c}`\alpha \,.\, \nu = \mathrm{N_0c}`\beta \,.\, \mathrm{Nc}`\alpha \geqslant \mathrm{Nc}`\beta$

In $*117{\cdot}2$, we repeat the Schröder-Bernstein theorem ($*73{\cdot}88$), which is required in most of the remaining propositions of this number. It leads at once to the propositions

$*117{\cdot}22$. $\vdash : \exists ! \, \mathrm{Cl}`\alpha \cap \mathrm{Nc}`\beta \, . \equiv . \, \mathrm{Nc}`\alpha \geqslant \mathrm{Nc}`\beta$

(which practically supersedes the definition of "$\geqslant$")

$*117{\cdot}221$. $\vdash : \mathrm{Nc}`\alpha \geqslant \mathrm{Nc}`\beta \, . \equiv . \, (\exists \rho) \, . \, \rho \subset \alpha \, . \, \rho \, \mathrm{sm} \, \beta$

$*117{\cdot}222$. $\vdash : \beta \subset \alpha \, . \supset . \, \mathrm{Nc}`\alpha \geqslant \mathrm{Nc}`\beta$

$*117{\cdot}23$. $\vdash : \mathrm{Nc}`\alpha \geqslant \mathrm{Nc}`\beta \, . \, \mathrm{Nc}`\beta \geqslant \mathrm{Nc}`\alpha \, . \equiv . \, \mathrm{Nc}`\alpha = \mathrm{Nc}`\beta$

This last proposition may be called the Schröder-Bernstein theorem with as much propriety as $*73{\cdot}88$; the two are scarcely different.

If we now revert to the definition of $\mu > \nu$, or to $*117{\cdot}13$, and apply $*117{\cdot}22$, we see ($*117{\cdot}26$) that "$\mathrm{Nc}`\alpha > \mathrm{Nc}`\beta$" may be conveniently regarded as asserting $\mathrm{Nc}`\alpha \geqslant \mathrm{Nc}`\beta \, . \sim (\mathrm{Nc}`\beta \geqslant \mathrm{Nc}`\alpha)$; in fact, the best ideas to work with are $\geqslant$ and its converse $\leqslant$, which for practical purposes we regard as defined by $*117{\cdot}22$, and from which we derive $>$ and $<$. The relation $>$ will be the product of $\geqslant$ into the negation of its converse; this holds for μ and ν ($*117{\cdot}281$) as well as for $\mathrm{Nc}`\alpha$ and $\mathrm{Nc}`\beta$.

$*117{\cdot}3{\cdot}31$ constitute an important use of $*110{\cdot}72$, namely to prove that one existent cardinal is greater than another or equal to it when the first can be obtained by adding to the second (where what is added must be a cardinal). That is to say, we have

$*117{\cdot}3$. $\vdash : \mathrm{Nc}`\alpha \geqslant \mathrm{Nc}`\beta \, . \equiv . \, (\exists \varpi) \, . \, \varpi \in \mathrm{NC} \, . \, \mathrm{Nc}`\alpha = \mathrm{Nc}`\beta +_c \varpi$

$*117{\cdot}31$. $\vdash :. \, \mu \geqslant \nu \, . \equiv : \mu, \nu \in \mathrm{N_0C} : (\exists \varpi) \, . \, \varpi \in \mathrm{NC} \, . \, \mu = \nu +_c \varpi$

$*117{\cdot}4$—$\cdot 471$ are concerned in proving that $>$ and $\geqslant$ are transitive, that $>$ is asymmetrical ($*117{\cdot}42$), and allied propositions.

Our next set of propositions is concerned with 0 and 1 and 2. We prove that a homogeneous cardinal is whatever is greater than or equal to 0 ($*117{\cdot}501$); that a homogeneous cardinal other than 0 is whatever is greater than 0 ($*117{\cdot}511$); that a homogeneous cardinal other than 0 is whatever is greater than or equal to 1 ($*117{\cdot}531$); and that a homogeneous cardinal other than 0 and 1 is whatever is greater than 1 ($*117{\cdot}55$), and is whatever is greater than or equal to 2 ($*117{\cdot}551$).

We next prove a set of propositions concerning $\geqslant$ which have no analogues for $>$, except when the cardinals concerned are finite. Thus *e.g.* we prove

$*117{\cdot}561$. $\vdash : \mu \geqslant \nu \, . \, \varpi \in \mathrm{N_0C} \, . \supset . \, \mu +_c \varpi \geqslant \nu +_c \varpi$

If we substitute $>$ for $\geqslant$, this no longer holds. Thus *e.g.* put $\mu = 2$, $\nu = 1$, $\varpi = \aleph_0$ (cf. $*123$); then $\mu > \nu$, but $\mu +_c \varpi = \nu +_c \varpi = \varpi$. Similar remarks apply to the analogous propositions ($*117{\cdot}571{\cdot}581{\cdot}591$) on multiplication and exponentiation.

We prove next that a sum is greater than or equal to either of its summands (∗117·6); that a product neither of whose factors vanishes is greater than or equal to either of its factors (∗117·62); that, assuming μ and ν are existent cardinals, then if they are neither 0 nor 1, their product is greater than or equal to their sum (∗117·631), and if μ is neither 0 nor 1, then $\mu^\nu \geqslant \mu \times_c \nu$ (∗117·652).

The last important proposition in this number is Cantor's theorem

∗117·661. $\vdash : \mu \in N_0C . \supset . 2^\mu > \mu$

which follows immediately from ∗102·72 and ∗116·72.

The propositions of this number are much used in the following section, on finite and infinite.

∗117·01. $\mu > \nu . = . (\exists \alpha, \beta) . \mu = N_0c`\alpha . \nu = N_0c`\beta .$
$\exists ! Cl`\alpha \cap Nc`\beta . \sim \exists ! Cl`\beta \cap Nc`\alpha$ Df

∗117·02. $\mu > Nc`\alpha . = . \mu > N_0c`\alpha$ Df

∗117·03. $Nc`\alpha > \nu . = . N_0c`\alpha > \nu$ Df

∗117·04. $\mu < \nu . = . \nu > \mu$ Df

∗117·05. $\mu \geqslant \nu . = : \mu > \nu . \vee . \mu, \nu \in N_0C . \mu = sm``\nu$ Df

∗117·06. $\mu \leqslant \nu . = . \nu \geqslant \mu$ Df

The analogues of ∗117·02·03 are to be applied also to ∗117·04·05·06.

∗117·1. $\vdash : \mu > \nu . \equiv . (\exists \alpha, \beta) . \mu = N_0c`\alpha . \nu = N_0c`\beta .$

GENERAL NOTE ON CARDINAL CORRELATORS

The correlators established at various stages throughout Section B present certain analogies to each other, and they or others closely resembling them will be found to be the correlators required in relation-arithmetic (Part IV). We shall therefore here collect together the most important propositions hitherto proved on correlators.

When we have to deal with correlators of two different functions of a single class, as *e.g.* $\epsilon_\Delta{}^{\backprime}\kappa$ and $\text{Prod}{}^{\backprime}\kappa$, the correlator is usually D or $\dot{s}$ or $\dot{s} \,|\, \text{D}$, with a suitable limitation on the converse domain. Sometimes it is $\breve{\iota} \,|\, \text{D}$ or $\epsilon \,|\, \text{D}$. Thus for example the class $\epsilon \downarrow {}^{\backprime\backprime}\kappa$, by means of which $\Sigma{}^{\backprime}\kappa$ is defined (*112), has double similarity with κ if $\kappa \,\epsilon\, \text{Cls}^2 \,\text{excl}$ (*112·14); in this case, the double correlator is $\breve{\iota} \,|\, \text{D}$ with its converse domain limited, *i.e.*

$$\vdash : \kappa \,\epsilon\, \text{Cls}^2 \,\text{excl} \,.\, \supset .\, \breve{\iota} \,|\, \text{D} \upharpoonright \Sigma{}^{\backprime}\kappa \,\epsilon\, \kappa \,\overline{\text{sm}}\, \overline{\text{sm}}\, (\epsilon \downarrow {}^{\backprime\backprime}\kappa).$$

In the case of $\text{Prod}{}^{\backprime}\kappa$ and $\epsilon_\Delta{}^{\backprime}\kappa$, the correlator is D, *i.e.*

$$\vdash : \kappa \,\epsilon\, \text{Cls}^2 \,\text{excl} \,.\, \supset .\, \text{D} \upharpoonright \epsilon_\Delta{}^{\backprime}\kappa \,\epsilon\, (\text{Prod}{}^{\backprime}\kappa) \,\overline{\text{sm}}\, (\epsilon_\Delta{}^{\backprime}\kappa).$$

In the case of $\epsilon_\Delta{}^{\backprime}s{}^{\backprime}\kappa$ and $\epsilon_\Delta{}^{\backprime}\epsilon_\Delta{}^{\backprime\backprime}\kappa$, the correlator is $\dot{s} \,|\, \text{D}$, *i.e.*

$$\vdash : \kappa \,\epsilon\, \text{Cls}^2 \,\text{excl} \,.\, \supset .\, \dot{s} \,|\, \text{D} \upharpoonright \epsilon_\Delta{}^{\backprime}\epsilon_\Delta{}^{\backprime\backprime}\kappa \,\epsilon\, (\epsilon_\Delta{}^{\backprime}s{}^{\backprime}\kappa) \,\overline{\text{sm}}\, (\epsilon_\Delta{}^{\backprime}\epsilon_\Delta{}^{\backprime\backprime}\kappa).$$

$\dot{s} \,|\, \text{D}$ also correlates $\epsilon_\Delta{}^{\backprime}\kappa$ with $\epsilon_\Delta{}^{\backprime}\epsilon \downarrow {}^{\backprime\backprime}\kappa$ (*85·61) and $P_\Delta{}^{\backprime}\alpha$ with $\epsilon_\Delta{}^{\backprime}P \downarrow {}^{\backprime\backprime}\alpha$ (*85·53), and $P_\Delta{}^{\backprime}s{}^{\backprime}\kappa$ with $\epsilon_\Delta{}^{\backprime}P_\Delta{}^{\backprime\backprime}\kappa$ (*85·27·42) if $\kappa \,\epsilon\, \text{Cls}^2 \,\text{excl}$.

The correlator of $(\alpha \uparrow \beta)_\Delta{}^{\backprime}\beta$ with $(\alpha \exp \beta)$ is $\dot{s}$ (*116·131).

Another kind of correlator arises where we are given a correlator of κ and λ, and we wish to construct a correlator for some associated classes $W{}^{\backprime}\kappa$ and $W{}^{\backprime}\lambda$, or where we are given correlators of α with γ and of β with δ, and we wish to construct a correlator of $\alpha \,♀\, \beta$ with $\gamma \,♀\, \delta$, where ♀ is some double descriptive function in the sense of *38. In this case, the correlator will usually be of the form $R \,\|\, \breve{S}$ (with a limited converse domain). Sometimes R and S will be identical; sometimes S will be R_ϵ. Such correlators always depend upon

***55·61.** $\vdash : \text{E} \,!\, R{}^{\backprime}x \,.\, \text{E} \,!\, S{}^{\backprime}y \,.\, \supset .\, (R \,\|\, \breve{S}){}^{\backprime}(x \downarrow y) = (R{}^{\backprime}x) \downarrow (S{}^{\backprime}y)$

together with the propositions *74·77 *seq.* giving cases in which $(R \,\|\, \breve{S}) \upharpoonright \lambda$ is a one-one relation. It follows from *55·61 that if R and S are correlators whose converse domains include the domain and converse domain respectively of a relation P, then $(R \,\|\, \breve{S}){}^{\backprime}P$ will be a relation holding between $R{}^{\backprime}x$ and $S{}^{\backprime}y$ whenever P holds between x and y. Examples of such correlators as $R \,\|\, \breve{S}$ are

***112·153.** $\vdash : T \,\epsilon\, \kappa \,\overline{\text{sm}}\,\overline{\text{sm}}\, \lambda \,.\, \supset .\, (T \,\|\, \breve{T}_\epsilon) \upharpoonright s{}^{\backprime}\epsilon \downarrow {}^{\backprime\backprime}\lambda \,\epsilon\, (\epsilon \downarrow {}^{\backprime\backprime}\kappa) \,\overline{\text{sm}}\, \overline{\text{sm}}\, (\epsilon \downarrow {}^{\backprime\backprime}\lambda)$

$*113{\cdot}127.\ \vdash : R \restriction \gamma \in \alpha\, \overline{\text{sm}}\, \gamma \,.\, S \restriction \delta \in \beta\, \overline{\text{sm}}\, \delta \,.\, \supset .$

$$(R \parallel \breve{S}) \restriction (\delta \times \gamma) \in (\alpha \underset{;}{\downarrow} {}``\beta)\, \overline{\text{sm}}\, \overline{\text{sm}}\, (\gamma \underset{;}{\downarrow} {}``\delta)$$

$*113{\cdot}65.\ \vdash .\ \downarrow z``\alpha \times \downarrow z``\beta = (\downarrow z \parallel \text{Cnv}`\downarrow z)``(\alpha \times \beta)$

$*114{\cdot}51.\ \vdash : T \restriction s`\lambda \in \kappa\, \overline{\text{sm}}\, \overline{\text{sm}}\, \lambda \,.\, \supset .\, (T \parallel \breve{T}_\epsilon) \restriction \epsilon_\Delta`\lambda \in (\epsilon_\Delta`\kappa)\, \overline{\text{sm}}\, (\epsilon_\Delta`\lambda)$

$*116{\cdot}192.\ \vdash : R \restriction \gamma \in \alpha\, \overline{\text{sm}}\, \gamma \,.\, S \restriction \delta \in \beta\, \overline{\text{sm}}\, \delta \,.\, \supset .$

$$(R \parallel \breve{S}) \restriction (\delta \times \gamma) \in (\alpha \exp \beta)\, \overline{\text{sm}}\, \overline{\text{sm}}\, (\gamma \exp \delta) \,.$$

$$(R \parallel \breve{S})_\epsilon \restriction (\gamma \exp \delta) \in (\alpha \exp \beta)\, \overline{\text{sm}}\, (\gamma \exp \delta)$$

An exceptionally simple correlator is given by

$*115{\cdot}502.\ \vdash : T \restriction s`\lambda \in \kappa\, \overline{\text{sm}}\, \overline{\text{sm}}\, \lambda \,.\, \supset .\, T \restriction s`\text{Prod}`\lambda \in (\text{Prod}`\kappa)\, \overline{\text{sm}}\, \overline{\text{sm}}\, (\text{Prod}`\lambda)$

Another exceptionally simple case is

$*73{\cdot}63.\ \vdash : S \in \alpha\, \overline{\text{sm}}\, \beta \,.\, T \restriction \alpha, T \restriction \beta \in 1 \to 1 \,.\, \alpha \cup \beta \subset \text{Ɑ}`T \,.\, \supset .$

$$T \mid S \mid \breve{T} \in (T``\alpha)\, \overline{\text{sm}}\, (T``\beta)$$

By means of the above correlators, most correlators that are required can be calculated. Thus it will be seen that $*116{\cdot}192$ in the above list is an immediate consequence of $*113{\cdot}127$ and $*115{\cdot}502$, since

$$\alpha \exp \beta = \text{Prod}`\alpha \underset{;}{\downarrow} {}``\beta \text{ and } s`\text{Prod}`\gamma \underset{;}{\downarrow} {}``\delta = \delta \times \gamma.$$

In order to develop the subject, it is almost always necessary, not merely to prove that two classes are similar, but actually to construct a correlator of the two classes. This applies equally to relation-arithmetic, in which analogous correlators are used to prove ordinal similarity.

SECTION C

FINITE AND INFINITE

Summary of Section C.

The distinction of finite and infinite is not required, as appears from Section B, for the definition of the arithmetical operations or for the proof of their formal laws. There are, however, many important respects in which finite cardinals and classes differ respectively from infinite cardinals and classes, and these differences must now be investigated.

There are two different ways in which we may define the finite and the infinite, and these two ways cannot (so far as is known at present) be shown to be equivalent except by assuming the multiplicative axiom. As there seems no good reason for regarding one of these ways as giving more exactly than the other what is usually meant by the words "finite" and "infinite," we shall, to avoid confusion, give other names than these to each of the two ways of dividing classes and cardinals. The division effected by the first method of definition we shall call the division into *inductive* and *non-inductive*; that effected by the second method we shall call the division into *non-reflexive* and *reflexive*.

The division into inductive and non-inductive, which is treated in $*120$, is defined as follows. An inductive cardinal is one which can be reached from 0 by successive additions of 1; that is, an inductive cardinal is one which has to 0 the relation $(+_0 1)_*$, where (by $*38{\cdot}02$) $+_0 1$ is the relation of $\alpha +_0 1$ to α, and the subscript asterisk has the meaning defined in $*90$. Hence we put

$$\mathrm{NC\,induct} = \hat{\alpha}\,\{\alpha\,(+_0 1)_*\,\dot{0}\} \quad \mathrm{Df.}$$

By applying the definition of $*90$, this gives

$$\vdash :: \alpha \,\epsilon\, \mathrm{NC\,induct} \,.\equiv :.\, \xi \,\epsilon\, \mu \,.\supset_\xi .\, \xi +_0 1 \,\epsilon\, \mu : 0 \,\epsilon\, \mu : \supset_\mu .\, \alpha \,\epsilon\, \mu.$$

This proposition may be regarded as stating that an inductive cardinal is one which obeys mathematical induction starting from 0, *i.e.* it is one which possesses every property possessed by 0 and by the numbers obtained by adding 1 to numbers possessing the property. In elementary mathematics, it is customary to regard mathematical induction, as applied to the series of natural numbers, as a principle rather than a definition, but according to

the above procedure it becomes a definition rather than a principle. This procedure is unavoidable as soon as it is perceived that there are cardinals which do not obey mathematical induction starting from 0. (This only holds on the assumption that the total number of objects in any one type is not one of the inductive cardinals. This assumption, in a slightly different form, is introduced below as the "axiom of infinity.") Thus for example $0 \neq 1$, and $\xi \neq \xi +_c 1 . \supset . \xi +_c 1 \neq \xi +_c 2$. Hence if α is any inductive cardinal, $\alpha \neq \alpha +_c 1$. But we know that $\aleph_0$, the first of Cantor's transfinite cardinals*, satisfies $\aleph_0 = \aleph_0 +_c 1$. Thus mathematical induction starting from 0 cannot be validly applied to prove properties of $\aleph_0$. It follows that the inductive cardinals as above defined are only some among cardinals; nor does it appear that there is any way of defining them except as those that obey mathematical induction starting from 0. It follows that mathematical induction is not a principle, to be either proved or assumed as an axiom, but is merely a characteristic defining a certain class of cardinals, namely the class of inductive cardinals.

By a syllogism in Barbara, it is evident that 0 is an inductive cardinal; hence by the definition 1 is an inductive cardinal, and hence 2, 3, ... are inductive cardinals. Thus any given cardinal in the series of natural numbers can be shown to be an inductive cardinal. The usual elementary properties of inductive cardinals, such as the uniqueness of subtraction and division, are easily proved by mathematical induction.

We define an inductive class as a class the number of whose terms is an inductive cardinal. More simply, we put

$$\text{Cls induct} = s\text{‘NC induct} \quad \text{Df.}$$

It is then easily shown that an inductive class is one which can be reached from Λ by successive additions of single members. That is, if we put

$$M = \hat{\eta}\hat{\zeta}\{(\exists y) . \zeta = \eta \cup \iota\text{‘}y\},$$

then $$\text{Cls induct} = \overleftarrow{M_*}\text{‘}\Lambda.$$

Thus we have

$$\vdash :: \rho \in \text{Cls induct} . \equiv :. \eta \in \mu . \supset_{\eta, y} . \eta \cup \iota\text{‘}y \in \mu : \Lambda \in \mu : \supset_\mu . \rho \in \mu.$$

We might equally well have begun by defining inductive classes, and proceeded to define inductive cardinals as the cardinals of inductive classes; in that case, we should have used the above relation M to define inductive classes.

Some of the properties which we expect inductive cardinals to possess, such for example as $\alpha \neq \alpha +_c 1$, can only be proved by assuming that no inductive cardinal is null, *i.e.* that

$$\alpha \in \text{NC induct} . \supset_\alpha . \exists ! \alpha.$$

This amounts to the assumption that, in any fixed type, a class can be found

* For the definition of $\aleph_0$, cf. $*123 \cdot 01$ and p. 186 of this summary.

having any assigned inductive number of terms. If this were false, there would have to be some definite member of the series of natural numbers which gave the total number of objects of the type in question. Thus suppose there were exactly n individuals in the universe, and no more, where n is an inductive cardinal. We should then have 2^n classes, 2^{2^n} classes of classes, and so on. In that case, in the type of individuals we should have $n +_c 1 = \Lambda$, $n +_c 2 = \Lambda$, etc. Hence we should have

$$n +_c 1 = (n +_c 1) +_c 1, \text{ etc.}$$

In the type of classes, we should get similar results for 2^n, and so on. It is plain (though not demonstrable except in each particular case) that if the assumption $\alpha \epsilon \mathrm{NC\ induct} . \supset_\alpha . \exists ! \alpha$ fails in any one type, it fails in any other type in the same hierarchy, and if it holds in any one, it holds in any other; for if n be the total number of individuals, then if n is an inductive cardinal, the total number of any other type is an inductive cardinal, while if n is not an inductive cardinal, no more is the total number of any other type. Hence the assumption $\alpha \epsilon \mathrm{NC\ induct} . \supset_\alpha . \exists ! \alpha$ is either true in any type or false in any type in one hierarchy. We shall call it the "axiom of infinity," putting

$$\mathrm{Infin\ ax} . = : \alpha \epsilon \mathrm{NC\ induct} . \supset_\alpha . \exists ! \alpha \quad \mathrm{Df.}$$

This assumption, like the multiplicative axiom, will be adduced as a hypothesis whenever it is relevant. It seems plain that there is nothing in logic to necessitate its truth or falsehood, and that it can only be legitimately believed or disbelieved on empirical grounds. When we wish to use a typically definite form of the axiom, we shall employ the definition

$$\mathrm{Infin\ ax}\,(x) . = : \alpha \epsilon \mathrm{NC\ induct} . \supset_\alpha . \exists ! \alpha\,(x) \quad \mathrm{Df},$$

which asserts that, if α is any inductive cardinal, there are at least α terms of the same type as x.

It is important to observe that, although the axiom of infinity cannot (so far as appears) be proved a priori, we can prove that any given inductive cardinal exists in a sufficiently high type. For if the total number of individuals be n, the numbers of objects in succeeding types are 2^n, 2^{2^n}, etc., and these numbers grow beyond any assigned inductive cardinal. Owing, however, to the fact that we cannot add together an infinite number of classes whose types increase without limit, we cannot hence show that there is a type in which every inductive cardinal exists, though we can show of every inductive cardinal that there is a type in which it exists. *I.e.* if α is any inductive cardinal, there must be a type for x such that $\exists ! \alpha\,(x)$ is true; but there need not be a type for x such that if α is any inductive cardinal, $\exists ! \alpha\,(x)$ is true.

The axiom of infinity suffices to prove the existence, in appropriate types, of $\aleph_0$, $2^{\aleph_0}$, $2^{2^{\aleph_0}}$, ... $\aleph_1$, $\aleph_2$, ...*. It does not suffice, so far as we know, to prove

* For the definitions of $\aleph_1$, $\aleph_2$, etc., see *265.

the existence of $\aleph_\omega$ or any Aleph with a greater suffix than ω, because the existences of $\aleph_1$, $\aleph_2$, ... are proved in successively rising types, and no meaning can be found for a type whose order is infinite.

The other definition of finite and infinite is of less importance in practice than the definition by induction. It is dealt with in *124. According to this definition, we call a class *reflexive* when it contains a proper part similar to itself, *i.e.* we put

$$\text{Cls refl} = \hat{\alpha}\{(\exists R) . R \epsilon 1 \to 1 . \text{D}`R = \alpha . \text{G}`R \subset \alpha . \text{G}`R \neq \alpha\} \quad \text{Df},$$

or, what comes to the same thing,

$$\text{Cls refl} = \hat{\alpha}\{(\exists R) . R \epsilon 1 \to 1 . \text{G}`R \subset \text{D}`R . \exists ! \overrightarrow{B}`R . \alpha = \text{D}`R\} \quad \text{Df}.$$

We call a cardinal reflexive when it is the homogeneous cardinal of a reflexive class, *i.e.* we put

$$\text{NC refl} = \text{N}_0\text{c}``\text{Cls refl} \quad \text{Df}.$$

It is easy to show that

$$\text{NC refl} = \hat{\alpha}\{\exists ! \alpha . \alpha = \alpha +_{\text{c}} 1\}.$$

We find that inductive classes and cardinals are non-reflexive, and reflexive classes and cardinals are non-inductive. We find also that reflexive cardinals are those that are equal to or greater than $\aleph_0$, while inductive cardinals are those that are less than $\aleph_0$. By assuming the multiplicative axiom, we can show that every cardinal is equal to, greater than, or less than $\aleph_0$, whence it follows that every cardinal is either reflexive or inductive, thus identifying the two definitions of finite and infinite. But so long as we refrain from assuming either the multiplicative axiom or some special axiom *ad hoc*, it remains possible (so far as is known at present) that there may be cardinals neither greater than, nor equal to, nor less than $\aleph_0$. Such cardinals, if they exist, are neither inductive nor reflexive: they are infinite if we define infinity by the negation of induction, but finite if we define infinity by reflexiveness. It is possible that further investigation may either prove or disprove the existence of such cardinals; for the present, their existence must remain an open question, except for those who regard the multiplicative axiom as a self-evident truth.

In *121 we shall consider *intervals* in a discrete series; *i.e.* in a series generated by a one-one relation between consecutive terms. If P be the generating relation of such a series, and x and y be two members of the series, of which y is the later, the terms which lie between x and y are the terms z for which we have

$$xP_{\text{po}}z . zP_{\text{po}}y,$$

where P_{po} has the meaning defined in *91. Hence we put

$$P(x - y) = \overleftarrow{P_{\text{po}}}`x \cap \overrightarrow{P_{\text{po}}}`y \quad \text{Df},$$

where "$P(x-y)$" means "the P-interval between x and y." We want also

symbols for the interval together with one or both of its end-points. For these we put

$$P(x \dashv y) = \overleftarrow{P_{\text{po}}}`x \cap \overrightarrow{P_*}`y \quad \text{Df},$$
$$P(x \vdash y) = \overleftarrow{P_*}`x \cap \overrightarrow{P_{\text{po}}}`y \quad \text{Df},$$
$$P(x \mapsto y) = \overleftarrow{P_*}`x \cap \overrightarrow{P_*}`y \quad \text{Df*}.$$

Thus, for example, if x and y be inductive cardinals, and P be the relation of n to $n +_c 1$, and $x < y$, $P(x - y)$ will be the numbers greater than x and less than y, while $P(x \dashv y)$ will be these numbers together with y, $P(x \vdash y)$ will be these numbers together with x, and $P(x \mapsto y)$ will be these numbers together with both x and y. By means of intervals, we define a class of relations P_ν (where ν is any inductive cardinal), where "$xP_\nu z$" means that we can pass from x to z in ν steps. In order to fit the case in which x and z are identical, and to insure that no relation such as P_ν shall hold between terms which do not both belong to the field of P, we put

$$P_\nu = \hat{x}\hat{y}\{\text{Nc}`P(x \mapsto y) = \nu +_c 1\} \quad \text{Df.}$$

Then, provided $P_{\text{po}} \subset J$, $P_0 = I \upharpoonright C`P$, and if further $P \in 1 \rightarrow 1$, then $P_1 = P$, $P_2 = P^2$, etc. If P is a transitive serial relation, P_1 is the relation "immediately preceding," which has great importance in well-ordered series. In this case, $P_1 = P \mathbin{\dot{-}} P^2$. If P is a transitive serial relation generating a finite series or a progression or a series of the type of the negative and positive integers in order of magnitude, we have

$$P = (P_1)_{\text{po}}.$$

In $*121$ we shall only consider P_ν in the case where

$$P \in (1 \rightarrow \text{Cls}) \cup (\text{Cls} \rightarrow 1),$$

and generally we shall have the further hypothesis $P_{\text{po}} \subset J$. We can then prove that the interval between x and y is always an inductive class (it will be null unless xP_*y); this proposition is useful in its application to the number-series and to progressions generally.

When $P \in (1 \rightarrow \text{Cls}) \cup (\text{Cls} \rightarrow 1) \,.\, P_{\text{po}} \subset J$, the class of such relations as P_ν (where ν is an inductive cardinal) is identical with Potid$`P$, the class of powers of P (cf. $*91$ *seq.*). This identification (which does not hold in general without the above hypothesis) leads to many useful propositions. In $*91$ *seq.*, we treated powers of a relation without the use of numbers, *i.e.* without defining the νth power of P. When the powers of P are the class of such relations as P_ν, we can of course take P_ν as the νth power of P. The general definition of the νth power of P (where ν is an inductive cardinal) will be given later, in $*301$; we shall denote it by P^ν, thereby including the notation P^2 already defined.

* These symbols are suggested by those given in Peano's *Formulaire*, Vol. IV. p. 116. (*Algèbre*, § 46.)

In $*122$ we shall deal with progressions, *i.e.* with series of the type of the series of natural numbers. In this number, we shall deal with such series as generated by one-one relations; they will be dealt with at a later stage ($*263$) as generated by transitive relations. We define a progression as a one-one relation whose domain is the posterity of its first term, *i.e.*

$$\text{Prog} = (1 \to 1) \cap \hat{R}(\text{D}`R = \overleftarrow{R_*}`B`R) \quad \text{Df.}$$

According to this definition, there must be a first term $B`R$; $\text{Ꭵ}`R$ will be $\breve{R}``\overleftarrow{R_*}`B`R$, *i.e.* $\overleftarrow{R_{\text{po}}}`B`R$, which is contained in $\overleftarrow{R_*}`B`R$, *i.e.* in $\text{D}`R$; since $\text{Ꭵ}`R \subset \text{D}`R$, every term of the field of $R$ has a successor, so that there is no end to the series; since $C`R = \text{D}`R = \overleftarrow{R_*}`B`R$, every term of the series can be reached from the beginning by successive steps. These characteristics suffice to define progressions.

In $*123$ we proceed to the definition and discussion of $\aleph_0$, the smallest of reflexive cardinals. This is the cardinal number of any class whose terms can be arranged in a progression; hence it is the class of domains of progressions, *i.e.* we may put

$$\aleph_0 = \text{D}``\text{Prog} \quad \text{Df.}$$

With this definition, remembering that Λ is a cardinal, we can prove that $\aleph_0$ is a cardinal; but to prove that $\aleph_0$ is an *existent* cardinal, we need the axiom of infinity. The existence-theorem for $\aleph_0$ is then derived from the inductive cardinals, which, if no one of them is null, form a progression when arranged in order of magnitude. It should be observed that this existence-theorem is for a higher type than that for which the axiom of infinity is assumed. In order to get an existence-theorem for the same type, we need the multiplicative axiom as well.

After a number on reflexive classes and cardinals ($*124$) and a number on the axiom of infinity ($*125$), the Section ends with a number ($*126$) on "typically indefinite inductive cardinals." The constant inductive cardinals are the typically ambiguous symbols 0, 1, 2, ...; thus we want to define the class of inductive cardinals in such a way that a variable member of the class shall be typically ambiguous. This is not possible without a sacrifice of rigour, but in $*126$ it is shown how to minimize the sacrifice of rigour, and how to obviate the resulting logical dangers. A variable whose values are typically ambiguous is said to be "typically indefinite."

A proof that all inductive cardinals exist has often been derived from $*120{\cdot}57$ (below). But according to the doctrine of types, this proof is invalid, since "$\mu +_c 1$" in $*120{\cdot}57$ is necessarily of higher type than "μ."

$*118$. ARITHMETICAL SUBSTITUTION AND UNIFORM FORMAL NUMBERS

Summary of $*118$.

A difficulty arises respecting substitution in arithmetic. For if μ is a formal number and its occurrence in $f\mu$ is arithmetical, then by IIT μ is always to be taken in an existential type. Hence we can only substitute a real variable ξ for μ under the hypothesis $\exists ! \xi$, and we can only substitute another formal number σ for μ provided that the equation $\mu = \sigma$, which justifies the substitution, is arithmetical, *i.e.* provided that in this equation the type of μ is such that $\exists ! \mu$.

The result is that the application of $*20 \cdot 18$ is apt to lead to fallacies owing to the different meanings which a formal number may possess in different occurrences. Hitherto we have considered each case in detail, *e.g.* note on $*110 \cdot 61$, and proof of $*110 \cdot 56$.

The condition for the safe application of $*20 \cdot 18$ is given in $*118 \cdot 01$, namely

$*118 \cdot 01$. $\vdash :. \exists ! \mu . \mu = \sigma . \supset : f\mu . \equiv . f\sigma$ $[*20 \cdot 18]$

This question is more fully discussed in the prefatory statement of this volume. The first reference to $*118 \cdot 01$ is in $*120 \cdot 222$. Another way of evading the difficulty is to work with formal numbers which, together with all their components, are of the same type. This leads to the consideration of Uniform Formal Numbers, which with the exception of $*118 \cdot 01$ occupies the rest of the number.

The *dominant type* of a formal number as used in any context is the type of the formal number itself in that context, and the *subordinate types* of the formal number are the dominant types of its component formal numbers.

When the dominant types of some of the formal numbers are not expressly indicated by an explicit notation (cf. $*65$), the rules according to which the dominant types thus left ambiguous are to be related, so far as they are related, including the rules governing the relation of subordinate types, if left ambiguous, to dominant types, are given by conventions IT, IIT, and AT of the prefatory statement in this volume.

We have now to consider an important special case which arises when types are explicitly indicated by the use of $*65 \cdot 01 \cdot 03$. A formal number, whose subordinate types are the same as its dominant type, is called *uniform*; and if some of its subordinate types are the same as its dominant type, it is called *partially uniform*. A formal number can only be partially uniform, or at least so designated as to be necessarily partially uniform, when the dominant type and those subordinate types identical with it are expressly indicated by

$*65 \cdot 01 \cdot 03$. For otherwise the conventions IT, IIT, and perhaps also AT, apply; and these do not secure uniformity, and may perhaps in some contexts be inconsistent with it.

Common sense in its consideration of arithmetic habitually disregards the possibility of a formal number representing Λ. In other words, it always applies conventions IIT and AT. But also, owing to its disregard of types, it assumes that the formal numbers are all uniform. The assumption which is really essential to this common sense reasoning, so far as the form of its arithmetical conclusions are concerned, is the assumption that none of the numerical symbols represent Λ. This assumption is secured here, when no types are expressly indicated, by IIT and AT. We have now to consider the effect on arithmetical operations of the other assumption, that the formal numbers are uniform, or partially uniform. There is no difficulty arising from any change of convention for symbolism, since, as stated above, partial or complete uniformity is secured by express indication of type. Accordingly conventions IT, IIT continue, as always, to apply when the types of formal numbers are left ambiguous.

Convention AT will not be applied either in $*118$ or $*119$ or $*120$: in $*118$ the fact is entirely unimportant since the dominant types of equational occurrences are always indicated, so that no case arises when it could apply.

Apart from its intrinsic interest and its bearing on substitution, the arithmetic of uniform formal numbers is necessary for $*120$, where the fundamental arithmetical properties of inductive numbers are investigated.

The propositions of this number are proved by the use of the results of $*117$. The basis of the reasoning is

$*118 \cdot 13$. $\vdash :. \mu \leqslant \nu . \supset : \exists ! \, \mathrm{sm}_\xi `` \nu . \supset . \exists ! \, \mathrm{sm}_\xi `` \mu$

In $*118 \cdot 2 \cdot 3 \cdot 4$ the meaning of the symbolism for dominant types is stated, namely

$*118 \cdot 2$. $\vdash . (\mu +_c \nu)_\xi = \hat{\eta} \{(\exists \alpha, \beta) . \mu = \mathrm{N_0c}`\alpha . \nu = \mathrm{N_0c}`\beta . \eta \, \mathrm{sm}_\xi \, (\alpha + \beta)\}$

$*118 \cdot 3$. $\vdash . (\mu \times_c \nu)_\xi = \hat{\eta} \{(\exists \alpha, \beta) . \mu = \mathrm{N_0c}`\alpha . \nu = \mathrm{N_0c}`\beta . \eta \, \mathrm{sm}_\xi \, (\alpha \times \beta)\}$

$*118 \cdot 4$. $\vdash . (\mu^\nu)_\xi = \hat{\eta} \{(\exists \alpha, \beta) . \mu = \mathrm{N_0c}`\alpha . \nu = \mathrm{N_0c}`\beta . \eta \, \mathrm{sm}_\xi \, (\alpha \exp \beta)\}$

The important propositions which are finally reached for addition are

$*118 \cdot 23$. $\vdash : \mu, \nu \in \mathrm{NC} . \supset . (\mu +_c \nu)_\xi = (\mathrm{sm}_\xi `` \mu +_c \mathrm{sm}_\xi `` \nu)_\xi$

$*118 \cdot 24$. $\vdash : \nu \in \mathrm{NC} . \supset . (\mu +_c \nu)_\xi = (\mu +_c \mathrm{sm}_\xi `` \nu)_\xi$

$*118 \cdot 241$. $\vdash : \mu \in \mathrm{NC} . \supset . (\mu +_c \nu)_\xi = (\mathrm{sm}_\xi `` \mu +_c \nu)_\xi$

$*118 \cdot 25$. $\vdash . (\mu +_c \nu +_c \varpi)_\xi = \{(\mu +_c \nu)_\xi +_c \varpi\}_\xi = \{\mu +_c (\nu +_c \varpi)_\xi\}_\xi$

The important propositions for multiplication are

$*118 \cdot 33$. $\vdash : \mu, \nu \in \mathrm{NC} - \iota`0 . \supset . (\mu \times_c \nu)_\xi = (\mathrm{sm}_\xi `` \mu \times_c \mathrm{sm}_\xi `` \nu)_\xi$

$*118 \cdot 34$. $\vdash : \nu \in \mathrm{NC} . \mu \neq 0 . \supset . (\mu \times_c \nu)_\xi = (\mu \times_c \mathrm{sm}_\xi `` \nu)_\xi$

***118·341.** $\vdash : \mu \in \mathrm{NC} \,.\, \nu \neq 0 \,.\, \supset \,.\, (\mu \times_c \nu)_\xi = (\mathrm{sm}_\xi``\mu \times_c \nu)_\xi$

***118·35.** $\vdash : \varpi \neq 0 \,.\, \supset \,.\, (\mu \times_c \nu \times_c \varpi)_\xi = \{(\mu \times_c \nu)_\xi \times_c \varpi\}_\xi$

***118·351.** $\vdash : \mu \neq 0 \,.\, \supset \,.\, (\mu \times_c \nu \times_c \varpi)_\xi = \{\mu \times_c (\nu \times_c \varpi)_\xi\}_\xi$

The important propositions for exponentiation are

***118·43.** $\vdash : \mu, \nu \in \mathrm{NC} - \iota`0 \,.\, \mu \neq 1 \,.\, \supset \,.\, (\mu^\nu)_\xi = \{(\mathrm{sm}_\xi``\mu)^{\mathrm{sm}_\xi``\nu}\}_\xi$

***118·44.** $\vdash : \nu \in \mathrm{NC} \,.\, \mu \neq 0 \,.\, \mu \neq 1 \,.\, \supset \,.\, (\mu^\nu)_\xi = (\mu^{\mathrm{sm}_\xi``\nu})_\xi$

***118·441.** $\vdash : \mu \in \mathrm{NC} \,.\, \nu \neq 0 \,.\, \supset \,.\, (\mu^\nu)_\xi = \{(\mathrm{sm}_\xi``\mu)^\nu\}_\xi$

***118·45.** $\vdash : \mu \neq 0 \,.\, \mu \neq 1 \,.\, \supset \,.\, (\mu^{\nu \times_c \varpi})_\xi = \{\mu^{(\nu \times_c \varpi)_\xi}\}_\xi$

***118·451.** $\vdash : \varpi \neq 0 \,.\, \supset \,.\, (\mu^{\nu \times_c \varpi})_\xi = [\{(\mu^\nu)_\xi\}^\varpi]_\xi$

***118·46.** $\vdash : \mu \neq 0 \,.\, \mu \neq 1 \,.\, \supset \,.\, (\mu^{\nu +_c \varpi})_\xi = \{\mu^{(\nu +_c \varpi)_\xi}\}_\xi$

***118·461.** $\vdash \,.\, (\mu^{\nu +_c \varpi})_\xi = \{(\mu^\nu)_\xi \times_c (\mu^\varpi)_\xi\}_\xi$

with two analogous propositions *118·462·463,

***118·47.** $\vdash : \varpi \neq 0 \,.\, \supset \,.\, \{(\mu \times_c \nu)^\varpi\}_\xi = [\{(\mu \times_c \nu)_\xi\}^\varpi]_\xi$

***118·471.** $\vdash :. \mu \neq 0 \,.\, \nu \neq 0 \,.\, \mathrm{v} \,.\, \varpi = 0 \,.\, \mathrm{v} \,.\, \sim(\mu, \nu, \varpi \in \mathrm{N_0C}) : \supset \,.$

$$\{(\mu \times_c \nu)^\varpi\}_\xi = \{(\mu^\varpi)_\xi \times_c (\nu^\varpi)_\xi\}_\xi$$

with two analogous propositions *118·472·473.

It is thus seen that, apart from some exceptional cases connected with 0 and 1, in all arithmetical operations uniform, or partially uniform, formal numbers can replace those constructed in obedience to convention IIT.

***118·01.** $\vdash :. \exists ! \mu \,.\, \mu = \sigma \,.\, \supset : f\mu \,.\, \equiv \,.\, f\sigma$ [*20·18]

As far as the symbolism is concerned, this proposition with the omission of $\exists ! \mu$ from the hypothesis is a transcript of *20·18. But if μ or σ (not excluding both) is a formal number, $\exists ! \mu$ is required in case the occurrence of μ in $f\mu$ is arithmetical. In fact this proposition embodies the three fundamental propositions of the Principle of Arithmetical Substitution arrived at in the Prefatory Explanations on Types. Its necessity arises from the convention IIT which is explained there.

***118·11.** $\vdash : \exists ! \mathrm{Nc}(\xi)`\beta \,.\, \alpha \subset \beta \,.\, \supset \,.\, \exists ! \mathrm{Nc}(\xi)`\alpha$

Dem.

[Proof as in *118·471, using *118·341]

$*119$. SUBTRACTION

Summary of $*119$.

The treatment of subtraction follows the same general lines as that of addition, and is simplified by the results in $*110$. A difficulty arises from the fact that subtraction (in any ordinary sense of the term) is not always possible; and also from the fact that the result, when possible, is not always a cardinal number.

We put

$*119\cdot01$. $\gamma -_c \nu = \hat{\xi}\{\text{Nc}`\xi +_c \nu = \gamma \,.\, \exists ! \,\text{Nc}`\xi +_c \nu\}$ Df

Thus when subtraction (in the ordinary sense of the term) is not possible,

$$\gamma -_c \nu = \Lambda.$$

The question of existential adjustment of types is dealt with by IIT of the prefatory statement combined with the following definitions:

$*119\cdot02$. $\text{Nc}`\alpha -_c \nu = \text{N}_0\text{c}`\alpha -_c \nu$ Df

$*119\cdot03$. $\gamma -_c \text{Nc}`\beta = \gamma -_c \text{N}_0\text{c}`\beta$ Df

We then proceed to deduce the elementary properties derivable from these definitions.

$*119\cdot11$. $\vdash : \exists ! \,\gamma -_c \nu \,.\, \supset \,.\, \gamma, \nu \in \text{N}_0\text{C}$

$*119\cdot12$. $\vdash : \xi \in \text{Nc}`\alpha -_c \text{Nc}`\beta \,.\, \equiv \,.\, \alpha \,\text{sm}\, \xi + \beta$

$*119\cdot14$. $\vdash : \xi \in \gamma -_c \nu \,.\, \supset \,.\, \text{N}_0\text{c}`\xi \subset \gamma -_c \nu$

$*119\cdot25$. $\vdash : \gamma \geqslant \nu \,.\, \supset \,.\, \exists ! \,(\gamma -_c \nu) \cap t_0`\gamma$

$*119\cdot26$. $\vdash : \exists ! \,\gamma -_c \nu \,.\, \supset \,.\, \gamma \geqslant \nu$

The next group of propositions is concerned with some simple results of subtraction.

$*119\cdot32$. $\vdash : (\gamma +_c \nu) -_c \nu \in \text{N}_0\text{C} \,.\, \supset \,.\, \text{sm}``\gamma = (\gamma +_c \nu) -_c \nu$

$*119\cdot34$. $\vdash : \gamma -_c \nu \in \text{N}_0\text{C} \,.\, \supset \,.\, (\gamma -_c \nu) +_c \nu = \text{sm}``\gamma$

$*119\cdot35$. $\vdash : \gamma -_c \nu \in \text{N}_0\text{C} \,.\, \supset \,.\, \alpha +_c \gamma = (\alpha +_c \nu) +_c (\gamma -_c \nu)$

Associative laws are then considered.

$*119\cdot44$. $\vdash : \mu +_c (\nu -_c \varpi) \subset (\mu +_c \nu) -_c \varpi$

$*119\cdot45$. $\vdash : (\mu +_c \nu) -_c \varpi \in \text{NC} \,.\, \exists ! \{\mu +_c (\nu -_c \varpi)\} \,.\, \supset \,.\, \mu +_c (\nu -_c \varpi) = (\mu +_c \nu) -_c \varpi$

The question of types is then dealt with:

$*119\cdot52$. $\vdash : \text{sm}_{\delta, \gamma}``(\mu -_c \nu)_\gamma = (\mu -_c \nu)_\delta \cap \text{D}`\text{sm}_{\delta, \gamma}$

A difficulty arises from the fact that if τ_1 and τ_2 are two complete types whose members are classes, we cannot prove that, either $\tau_1 = \text{sm}``\tau_2$ or $\tau_2 = \text{sm}``\tau_1$. We put

$*119{\cdot}54.\quad \text{SM}(\delta,\gamma) \,.\!=:\, t`\delta = \text{D}`\text{sm}_{\delta,\gamma} \,.\vee.\, t`\gamma = \text{D}`\text{sm}_{\gamma,\delta} \quad \text{Df}$

Then we obtain

$*119{\cdot}541.\ \vdash : \text{SM}(\delta,\gamma) \,.\, (\mu -_c \nu)_\gamma \,\epsilon\, \text{N}_0\text{C} \,.\, (\mu -_c \nu)_\delta \,\epsilon\, \text{NC} \,.\supset.$

$$\text{sm}_{\delta,\gamma}``(\mu -_c \nu)_\gamma = (\mu -_c \nu)_\delta$$

Finally we show that any existential adjustment of types will suffice for the components:

$*119{\cdot}61.\quad \vdash : \mu \,\epsilon\, \text{N}_0\text{C} \,.\, \exists!\, \text{sm}_\xi``\mu \,.\supset.\, \mu -_c \nu = \text{sm}_\xi``\mu -_c \nu$

$*119{\cdot}62.\quad \vdash : \nu \,\epsilon\, \text{N}_0\text{C} \,.\, \exists!\, \text{sm}_\xi``\nu \,.\supset.\, \mu -_c \nu = \mu -_c \text{sm}_\xi``\nu$

Also $*119{\cdot}25{\cdot}26$ are now extended to

$*119{\cdot}64.\quad \vdash :.\, \exists!\, \text{sm}_\xi``\mu \,.\supset : \mu \geqslant \nu \,.\equiv.\, \exists!\, (\mu -_c \nu)_\xi$

The only applications of the propositions of this number are in connection with Inductive Cardinals (cf. $*120$).

$*119{\cdot}01.\quad \gamma -_c \nu = \hat{\xi}\{\text{Nc}`\xi +_c \nu = \gamma \,.\, \exists!\, \text{Nc}`\xi +_c \nu\} \quad \text{Df}$

Here the suffix to the sign of subtraction is introduced to show that we are concerned with *cardinal* subtraction. It will be found that $\gamma -_c \nu$ is not an NC except under hypotheses for γ and ν.

$*119{\cdot}02.\quad \text{Nc}`\alpha -_c \nu = \text{N}_0\text{c}`\alpha -_c \nu \quad \text{Df}$

$*119{\cdot}03.\quad \gamma -_c \text{Nc}`\beta = \gamma -_c \text{N}_0\text{c}`\beta \quad \text{Df}$

$*119{\cdot}04.\quad \vdash .\, \text{Nc}`\alpha -_c \text{Nc}`\beta = \text{N}_0\text{c}`\alpha -_c \text{N}_0\text{c}`\beta \quad [*119{\cdot}02{\cdot}03]$

Note that the occurrence of a formal number in the place of γ or ν in $\gamma -_c \nu$ is an arithmetic occurrence, and accordingly IIT applies to it.

$*119{\cdot}1.\quad \vdash : \xi \,\epsilon\, \gamma -_c \nu \,.\equiv.\, \text{Nc}`\xi +_c \nu = \gamma \,.\, \exists!\, \text{Nc}`\xi +_c \nu \quad [(*119{\cdot}01)]$

$*119{\cdot}101.\ \vdash : \xi \,\epsilon\, \text{Nc}`\alpha -_c \nu \,.\equiv.\, \text{Nc}`\xi +_c \nu = \text{N}_0\text{c}`\alpha \quad [(*119{\cdot}02) \,.\, *103{\cdot}13]$

$*119{\cdot}102.\ \vdash : \xi \,\epsilon\, \gamma -_c \text{Nc}`\beta \,.\equiv.\, \text{Nc}`\xi +_c \text{Nc}`\beta = \gamma \,.\, \exists!\, \text{Nc}`\xi +_c \text{Nc}`\beta$
$[(*119{\cdot}03) \,.\, *110{\cdot}3]$

$*119{\cdot}103.\ \vdash : \xi \,\epsilon\, \text{Nc}`\alpha -_c \text{Nc}`\beta \,.\equiv.\, \text{Nc}`\xi +_c \text{Nc}`\beta = \text{N}_0\text{c}`\alpha$
$[*119{\cdot}04 \,.\, *110{\cdot}3 \,.\, *103{\cdot}13]$

$*119{\cdot}11.\quad \vdash : \exists!\, \gamma -_c \nu \,.\supset.\, \gamma, \nu \,\epsilon\, \text{N}_0\text{C} \quad [*110{\cdot}4{\cdot}42 \,.\, *103{\cdot}34]$

$*119{\cdot}12.\quad \vdash : \xi \,\epsilon\, \text{Nc}`\alpha -_c \text{Nc}`\beta \,.\equiv.\, \alpha \,\text{sm}\, \xi + \beta$

Dem.

$$\begin{aligned}
&\vdash .\, *119{\cdot}103 \,.\supset \vdash : \xi \,\epsilon\, \text{Nc}`\alpha -_c \text{Nc}`\beta \,.\equiv.\, \text{Nc}`\xi +_c \text{Nc}`\beta = \text{N}_0\text{c}`\alpha \,. \\
&[*110{\cdot}3] \qquad\qquad \equiv.\, \text{Nc}`(\xi + \beta) = \text{N}_0\text{c}`\alpha \,. \\
&[*100{\cdot}35 . *103{\cdot}13] \qquad\qquad \equiv.\, \alpha \,\text{sm}\, \xi + \beta : \supset \vdash .\, \text{Prop}
\end{aligned}$$

Thus $\text{Nc}`\alpha -_c \text{Nc}`\beta$ is an NC when $\hat{\xi}(\alpha \,\text{sm}\, \xi + \beta)$ is an NC.

***119·13.** $\vdash : \mathrm{N_0c}`\gamma \subset \mathrm{Nc}`\alpha -_c \mathrm{Nc}`\beta \,.\equiv.\, \alpha \,\mathrm{sm}\, (\gamma + \beta)$

Dem.

The penultimate step in the proof employs the principle, explained in the prefatory statement, that, since in the previous line the equation

$$\mathrm{Nc}`\xi +_c \nu = \gamma +_c \nu$$

has its sides undetermined in type by the conventions IT and IIT, any convenient type can be chosen for them. The type chosen in this line is such that $\exists ! \gamma +_c \nu$, and the references indicate the existence of at least one such type.

$*120$. INDUCTIVE CARDINALS

Summary of $*120$.

Inductive Cardinals are those that obey mathematical induction starting from 0, *i.e.* in the language of Part II, Section E, they are the posterity of 0 with respect to the relation of ν to $\nu +_0 1$, or, in more popular language, they are those that can be reached from 0 by successive additions of 1. In former days, these were supposed to be all the cardinals, and mathematical induction was treated as a kind of self-evident axiom. We now know that only certain cardinals obey mathematical induction starting from 0. It is these cardinals which are to be considered in this number. They embrace 0, 1, 2, ... and generally all those cardinals which would be commonly called finite, all those which can be expressed in the usual Arabic system of numeration, and no others. The propositions to be proved concerning them in this number are elementary and familiar; the interest lies entirely in the definition and method of proof, not in the propositions themselves.

Put $\qquad \text{NC induct} = \hat{\alpha}\{\alpha(+_0 1)_* 0\} \quad \text{Df.}$

Since $(+_0 1)_*$ has necessarily its domain and converse domain of the same type, it is important to be careful in noting the relations of type. Accordingly we also put

$$\text{N}_\xi\text{C induct} = \hat{\alpha}\{\alpha(+_0 1)_* 0_\xi\} \quad \text{Df.}$$

We begin by applying the propositions of $*90$. Thus we have

$*120{\cdot}11$. $\vdash :. \alpha \epsilon \text{N}_\eta\text{C induct} : \phi\xi . \supset_\xi . \phi(\xi +_0 1) : \phi 0_\eta : \supset . \phi\alpha$

$*120{\cdot}12$. $\vdash . 0 \epsilon \text{NC induct}$

$*120{\cdot}121$. $\vdash : \alpha \epsilon \text{N}_\xi\text{C induct} . \supset . (\alpha +_0 1)_\xi \epsilon \text{N}_\xi\text{C induct}$

$*120{\cdot}13$. $\vdash :. \alpha \epsilon \text{N}_\eta\text{C induct} : \xi \epsilon \text{N}_\eta\text{C induct} . \phi\xi . \supset_\xi . \phi(\xi +_0 1) : \phi 0_\eta : \supset . \phi\alpha$

$*120{\cdot}15$. $\vdash : \alpha \epsilon \text{NC induct} . \exists ! \alpha . \supset . \text{sm}``\alpha \epsilon \text{NC induct}$

$*120{\cdot}151$. $\vdash : \alpha \epsilon \text{NC induct} . \exists ! \alpha . \supset . \alpha +_0 1 \epsilon \text{NC induct}$

$*120{\cdot}152$. $\vdash : \alpha \epsilon \text{NC} . \text{sm}``\alpha \epsilon \text{NC induct} - \iota`\Lambda . \supset . \alpha \epsilon \text{NC induct} - \iota`\Lambda$

We then proceed to deduce the elementary properties of inductive *classes*, putting

$$\text{Cls induct} = s`\text{NC induct}.$$

We have

$*120{\cdot}21$. $\vdash : \rho \epsilon \text{Cls induct} . \equiv . \text{N}_0\text{c}`\rho \epsilon \text{NC induct}$

$*120{\cdot}211$. $\vdash : \text{Nc}`\rho \epsilon \text{NC induct} - \iota`\Lambda . \supset . \rho \epsilon \text{Cls induct}$

(We do not have an equivalence here, because, for aught we know, it might be possible to determine the ambiguity of $\text{Nc}`\rho$ so that $\text{Nc}`\rho = \Lambda$, even when $\rho \epsilon \text{Cls induct}$. This will not be possible, however, if the axiom of infinity is assumed.)

$*120{\cdot}212{\cdot}213.$ $\vdash . \Lambda, \iota`x \in \text{Cls induct}$

$*120{\cdot}214.$ $\vdash :. \rho \,\text{sm}\, \sigma . \supset : \rho \in \text{Cls induct} . \equiv . \sigma \in \text{Cls induct}$

We have a set of propositions applying induction to classes *directly*, and not through the intermediary of cardinals. Thus we have

$*120{\cdot}251.$ $\vdash : \eta \in \text{Cls induct} . \supset . \eta \cup \iota`y \in \text{Cls induct}$

$*120{\cdot}26.$ $\vdash :. \rho \in \text{Cls induct} : \phi\eta . \supset_{\eta, x} . \phi(\eta \cup \iota`x) : \phi\Lambda : \supset . \phi\rho$

We then state the axiom of infinity, and prove ($*120{\cdot}33$) that it is equivalent to the assumption that if α is an inductive cardinal, $\alpha \neq \alpha +_c 1$. To prove this, we first prove various propositions about $\alpha +_c 1$, among others the following:

$*120{\cdot}311.$ $\vdash : \exists ! \alpha +_c 1 . \alpha +_c 1 = \beta +_c 1 . \supset . \alpha = \text{sm}``\beta . \exists ! \alpha$

$*120{\cdot}322.$ $\vdash :. \alpha \in \text{NC induct} . \supset : \exists ! \alpha . \equiv . \alpha \neq \alpha +_c 1$

We then proceed to consider subtraction ($*120{\cdot}41$—$\cdot418$), which only gives a cardinal number when the subtrahend is an inductive cardinal. We have

$*120{\cdot}41.$ $\vdash :. \nu \in \text{NC induct} . \exists ! \alpha +_c \nu . \supset : \alpha +_c \nu = \beta +_c \nu . \supset . \alpha = \text{sm}``\beta$

We might validly put $\alpha = \beta$ instead of $\alpha = \text{sm}``\beta$, since $\alpha = \beta$ will be true whenever it is significant.

We have

$*120{\cdot}411.$ $\vdash :. \nu \in \text{NC induct} . \supset :$

$$\exists ! \gamma -_c \nu . \supset . \gamma -_c \nu \in \text{N}_0\text{C} : \gamma \geqslant \nu . \equiv . (\gamma -_c \nu) \cap t_0`\gamma \in \text{N}_0\text{C}$$

$*120{\cdot}4111.$ $\vdash :. \nu \in \text{NC induct} . \exists ! \text{sm}_\xi``\gamma . \supset : \gamma \geqslant \nu . \equiv . (\gamma -_c \nu)_\xi \in \text{N}_0\text{C}$

Hence we arrive at the conditions requisite for the usual point of view of subtraction; namely,

$*120{\cdot}412.$ $\vdash : \nu \in \text{NC induct} . \gamma \geqslant \nu . \exists ! \text{sm}_\xi``\gamma . \supset . (\gamma -_c \nu)_\xi = \{(\imath\alpha)(\alpha +_c \nu = \gamma)\}_\xi$

Also from $*120{\cdot}4111$ we deduce

$*120{\cdot}414.$ $\vdash : \mu \in \text{N}_0\text{C} - \iota`0 . \exists ! \text{sm}_\xi``\mu . \supset . (\mu -_c 1)_\xi \in \text{N}_0\text{C}$

And from $*120{\cdot}411 . *119{\cdot}34$, we find

$*120{\cdot}416.$ $\vdash : \nu \in \text{NC induct} . \exists ! \gamma -_c \nu . \supset . (\gamma -_c \nu) +_c \nu = \text{sm}``\gamma$

We prove next that no proper part of an inductive class is similar to the whole ($*120{\cdot}426$), *i.e.* that inductive classes are non-reflexive, and various connected propositions, *e.g.*

$*120{\cdot}423.$ $\vdash : \alpha \in \text{N}_\eta\text{C induct} - \iota`0 . \equiv . (\exists\beta) . \beta \in \text{N}_\eta\text{C induct} . \alpha = (\beta +_c 1)_\eta$

$*120{\cdot}4232.$ $\vdash : \alpha \in \text{N}_\eta\text{C induct} - \iota`0 . \equiv . (\exists\beta) . \beta \in \text{N}_\eta\text{C induct} - \iota`\Lambda . \alpha = (\beta +_c 1)_\eta$

$*120{\cdot}428.$ $\vdash : \nu \in \text{NC induct} . \exists ! \alpha +_c \nu . \alpha \neq 0 . \supset . \alpha +_c \nu > \nu$

$*120{\cdot}429.$ $\vdash :. \nu \in \text{NC induct} . \supset : \mu > \nu . \equiv . \mu \geqslant \nu +_c 1$

The last two of the above propositions do not hold in general when ν is a cardinal which is not inductive.

We prove next that if α is an existent inductive cardinal, then any existent cardinal is greater than, equal to, or less than α (*120·441); that if α, β are inductive cardinals, so is $\alpha +_c \beta$ (*120·45·450), and if $\alpha +_c \beta$ is an inductive cardinal other than Λ, so are α and β (*120·452). We then have some propositions dealing with mathematical induction starting from 1 or 2, *e.g.*

***120·4622.** $\vdash :. \alpha \in \mathrm{NC} . \beta \in \mathrm{NC}(\eta) . \exists ! \, \mathrm{sm}_\xi ``\beta . \supset :$
$$\beta \, (+_c 1)_* \, \mathrm{sm}_\eta ``\alpha . \equiv . \mathrm{sm}_\xi ``\beta \, (+_c 1)_* \, \mathrm{sm}_\xi ``\alpha$$

***120·47.** $\vdash :: \beta \in \mathrm{N}_\eta \mathrm{C} \, \mathrm{induct} - \iota`0 . \equiv :. \xi \in \mu . \supset_\xi . (\xi +_c 1)_\eta \in \mu : 1_\eta \in \mu : \supset_\mu . \beta \in \mu$

From *120·452 we deduce

***120·48.** $\vdash : \beta \in \mathrm{NC} \, \mathrm{induct} . \beta \geqslant \alpha . \supset . \alpha \in \mathrm{NC} \, \mathrm{induct} - \iota`\Lambda$

so that any number less than an inductive number is inductive. Hence

***120·481.** $\vdash : \eta \in \mathrm{Cls} \, \mathrm{induct} . \xi \subset \eta . \supset . \xi \in \mathrm{Cls} \, \mathrm{induct}$

which is a proposition constantly used, and

***120·491.** $\vdash :. \xi \sim\in \mathrm{Cls} \, \mathrm{induct} . \equiv : \beta \in \mathrm{NC} \, \mathrm{induct} . \supset_\beta . \exists ! \, \beta \cap \mathrm{Cl}`\xi$

We then prove that if α, β are inductive cardinals, $\alpha \times_c \beta$ and α^β are either inductive cardinals or Λ (*120·5·52), while conversely if $\alpha \times_c \beta$ or α^β is an existent inductive cardinal, α and β are so also, with exceptions for 0 and 1 (*120·512·56·561). Hence we infer the uniqueness of division and the taking of roots (*120·51·53·55) so long as inductive numbers are concerned.

We have next a set of propositions on the axiom of infinity and the multiplicative axiom. We prove (*120·61) that if there is any existent cardinal which is not inductive, the axiom of infinity is true. From *83·9·904, we infer by induction that if κ is an inductive class of which Λ is not a number, $\epsilon_\Delta`\kappa$ exists (*120·62), whence it follows that either the multiplicative axiom or the axiom of infinity must be true (*120·64).

Finally, we have a set of propositions on inductive *classes*. We prove

***120·71.** $\vdash : \rho, \sigma \in \mathrm{Cls} \, \mathrm{induct} . \equiv . \rho \cup \sigma \in \mathrm{Cls} \, \mathrm{induct} . \equiv . \rho + \sigma \in \mathrm{Cls} \, \mathrm{induct}$

***120·74.** $\vdash : \rho \in \mathrm{Cls} \, \mathrm{induct} . \equiv . \mathrm{Cl}`\rho \in \mathrm{Cls} \, \mathrm{induct}$

***120·75.** $\vdash : s`\kappa \in \mathrm{Cls} \, \mathrm{induct} . \equiv . \kappa \in \mathrm{Cls} \, \mathrm{induct} . \kappa \subset \mathrm{Cls} \, \mathrm{induct}$

with analogous propositions (involving however a hypothesis as to κ) on the subject of $\epsilon_\Delta`\kappa$.

The propositions of the present number are essential to the ordinary arithmetic of finite numbers. In the present work, however, they are not much used after the present section until we reach Part V, Section E, where we deal with the ordinal theory of finite and infinite.

∗120·01. $\text{NC induct} = \hat{\alpha}\{\alpha\,(+_c 1)_* \,0\}$ Df

Note that in virtue of our general conventions for descriptive functions of two arguments (∗38),

$$+_c 1 = \hat{\alpha}\hat{\beta}\,(\alpha = \beta +_c 1).$$

That is, $+_c 1$ is the relation of a cardinal to its immediate predecessor. It is the number written in the usual mathematical notation as $+1$ in the series of positive and negative integers, just as its converse is the number -1. (It should be observed that if ν is any cardinal, $+\nu$ is not identical with ν, since $+\nu$ is a relation, while ν is a class of classes.)

∗120·011. $\text{N}_\xi\text{C induct} = \hat{\alpha}\{\alpha\,(+_c 1)_* \,0_\xi\}$ Df

All members of N_ξC induct belong to the same type as 0_ξ, so that, if α is any member of N_ξC induct, "$\xi \in \alpha$" is significant.

∗120·02. $\text{Cls induct} = s\text{‘NC induct}$ Df

∗120·021. $\text{Cls}_\xi\,\text{induct} = s\text{‘N}_\xi\text{C induct}$ Df

In virtue of these definitions an inductive class is one whose cardinal is an inductive cardinal.

∗120·03. $\text{Infin ax} \,.=:\, \alpha \in \text{NC induct} \,.\supset_\alpha .\, \exists!\,\alpha$ Df

"Infin ax," like "Mult ax," is an arithmetical hypothesis which some will consider self-evident, but which we prefer to keep as a hypothesis, and to adduce in that form whenever it is relevant. Like "Mult ax," it states an existence-theorem. In the above form, it states that, if α is any inductive cardinal, there is at least one class (of the type in question) which has α terms. An equivalent assumption would be that, if ρ is any inductive class, there are objects which are not members of ρ. For in that case, if x be such an object, $\text{Nc‘}(\rho \cup \iota\text{‘}x) = \text{Nc‘}\rho +_c 1$. Hence by induction, every inductive cardinal must exist. Another equivalent assumption would be that V (the class of all objects of the type in question) is not an inductive class. The assumption that $\aleph_0$ exists in the type in question is, as we shall see, a stronger assumption than the above, unless we assume the multiplicative axiom.

If the axiom of infinity is true, the inductive cardinals are all different one from another, *i.e.* $\alpha +_c \beta$, where α and β are inductive cardinals, is not equal to α unless $\beta = 0$. But if the axiom of infinity is false, then, in any assigned type, all the cardinals after a certain one are Λ. (Except in the lowest type, the last existent cardinal must be a power of 2.) That is, if (say) 8 were the largest existent cardinal in the type in question, we should have, in that type, $9 = \Lambda$, and the same would hold of 10, 11, ... This possibility has to be taken account of in what follows.

In order to give typical definiteness to the axiom of infinity, we write

***120·04.** Infin ax $(x) . = : \alpha \epsilon \text{NC induct} . \supset_\alpha . \exists ! \alpha (x)$ Df

Then "Infin ax (x)" states that, if α is any inductive cardinal, there are at least α objects of the same type as x.

***120·1.** $\vdash : \alpha \epsilon \text{NC induct} . \equiv . \alpha (+_c 1)_* 0$ [(*120·01)]

***120·101.** $\vdash :: \alpha \epsilon \text{NC induct} . \equiv :. \xi \epsilon \mu . \supset_\xi . \xi +_c 1 \epsilon \mu : 0 \epsilon \mu : \supset_\mu . \alpha \epsilon \mu$
[*120·1 . *90·131 . *38·12]

The right-hand side of the above equivalence gives the usual formula for mathematical induction. Observe that the conditions of significance require that $\xi +_c 1$ should be taken in the same type as ξ. This fact is specially relevant in the proof of *120·15.

The symbol "NC induct" is of ambiguous type not necessarily the same in different occurrences; also, according to the convention explained in the prefatory statement as holding for NC and NC induct, "$\alpha, \beta \epsilon \text{NC induct}$" will not imply that α and β are of the same type. Accordingly to avoid error in connection with *120·1·101 typical definiteness is required as in the three following propositions.

***120·102.** $\vdash : \alpha \epsilon \text{N}_\eta\text{C induct} . \equiv . \alpha (+_c 1)_* 0_\eta$ [(*120·011)]

***120·103.** $\vdash :: \alpha \epsilon \text{N}_\eta\text{C induct} . \equiv :. \xi \epsilon \mu . \supset_\xi . (\xi +_c 1)_\eta \epsilon \mu : 0_\eta \epsilon \mu : \supset_\mu . \alpha \epsilon \mu$
[*120·101]

***120·11.** $\vdash :. \alpha \epsilon \text{N}_\eta\text{C induct} : \phi\xi . \supset_\xi . \phi (\xi +_c 1) : \phi 0_\eta : \supset . \phi\alpha$
[*120·102 . *90·112]

***120·12.** $\vdash . 0 \epsilon \text{NC induct}$ $\left[*120{\cdot}101 \frac{0}{\alpha}\right]$

***120·121.** $\vdash : \alpha \epsilon \text{N}_\xi\text{C induct} . \supset . (\alpha +_c 1)_\xi \epsilon \text{N}_\xi\text{C induct}$ [*90·172 . *120·102]

By means of this proposition and *120·12, any assigned cardinal in the series of natural numbers can be shown to be an inductive cardinal; thus *e.g.* to show that 27 is an inductive cardinal, we shall only have to use *120·121 twenty-seven times in succession.

***120·122.** $\vdash . 1 \epsilon \text{NC induct}$ [*120·12·121 . *110·641]

***120·123.** $\vdash . 2 \epsilon \text{NC induct}$. etc. [*120·122·121 . *110·643]

***120·124.** $\vdash . \alpha +_c 1 \neq 0$

Dem.

$\vdash . *110{\cdot}4 . \text{Transp} . \supset \vdash : \alpha \sim\epsilon \text{NC} . \supset . \alpha +_c 1 = \Lambda .$
[*101·12] $\supset . \alpha +_c 1 \neq 0$ (1)
$\vdash . *110{\cdot}632 . \supset \vdash :. \alpha \epsilon \text{NC} . \supset : \xi \epsilon \alpha +_c 1 . \supset . \exists ! \xi :$
[*24·63] $\supset : \Lambda \sim\epsilon \alpha +_c 1 :$
[*54·102] $\supset : \alpha +_c 1 \neq 0$ (2)
$\vdash . (1) . (2) . \supset \vdash . \text{Prop}$

$*120\cdot13$. $\vdash :. \alpha \in N_\eta C \text{ induct} : \xi \in N_\eta C \text{ induct} . \phi\xi . \supset_\xi . \phi(\xi +_c 1) : \phi 0_\eta : \supset . \phi\alpha$

Dem.

$\vdash . *120\cdot121 . \supset \vdash :. \xi \in N_\eta C \text{ induct} . \phi\xi . \supset_\xi . \phi(\xi +_c 1) : \supset :$
$$\xi \in N_\eta C \text{ induct} . \phi\xi . \supset_\xi . (\xi +_c 1)_\eta \in N_\eta C \text{ induct} . \phi(\xi +_c 1) \quad (1)$$
$\vdash . *120\cdot12 . \supset \vdash : \phi 0_\eta . \supset . 0_\eta \in N_\eta C \text{ induct} . \phi 0_\eta \quad (2)$

$\vdash . (1) . (2) . \supset \vdash :. \text{Hp} . \supset :$

$\xi \in N_\eta C \text{induct} . \phi\xi . \supset_\xi . (\xi +_c 1)_\eta \in N_\eta C \text{induct} . \phi(\xi +_c 1) : 0_\eta \in N_\eta C \text{ induct} . \phi 0_\eta :$

$\left[*120\cdot11 \dfrac{\xi \in N_\eta C \text{ induct} . \phi\xi}{\phi\xi}\right] \supset : \alpha \in N_\eta C \text{ induct} . \phi\alpha :. \supset \vdash . \text{Prop}$

The above proposition is often convenient for inductive proofs.

$*120\cdot14$. $\vdash . \text{NC induct} \subset \text{NC}$

Dem.

$\vdash . *110\cdot42 . \text{Simp} . \supset \vdash : \alpha \in \text{NC} . \supset . \alpha +_c 1 \in \text{NC} \quad (1)$

$\vdash . (1) . *101\cdot11 . *120\cdot11 \dfrac{\alpha \in \text{NC}}{\phi\alpha} . \supset \vdash . \text{Prop}$

This proposition does not show that every inductive cardinal is an *existent* cardinal; to obtain this, we require the axiom of infinity.

$*120\cdot15$. $\vdash : \alpha \in \text{NC induct} . \exists ! \alpha . \supset . \text{sm}``\alpha \in \text{NC induct}$

I.e. a cardinal which is not null and is inductive in any one type is also inductive in any other type.

Dem.

$\vdash . *101\cdot15 . *120\cdot12 . \supset \vdash . \text{sm}_\eta``0_\xi \in N_\eta C \text{ induct} \quad (1)$

$[*120\cdot15] \quad \supset . \alpha \in \text{NC induct} \quad (1)$

$\vdash . *37\cdot29 . \supset \vdash : \text{Hp} . \supset . \exists ! \alpha \quad (2)$

$\vdash . (1) . (2) . \supset \vdash . \text{Prop}$

The following propositions, giving alternative forms for the definition of inductive *classes*, are inserted in order to show that the theory of inductive classes might be treated in a less arithmetical manner than we have adopted.

***120·2.** $\vdash : \rho \in \text{Cls induct} . \equiv . (\exists \alpha) . \alpha \in \text{NC induct} . \rho \in \alpha$ [(*120·02)]

***120·201.** $\vdash :. \rho \,\text{sm}\, \sigma . \supset : \text{N}_0\text{c}`\rho \in \text{NC induct} . \equiv . \text{N}_0\text{c}`\sigma \in \text{NC induct}$

Dem.

$\vdash . *100·35 . *103·13 . *100·511 . \supset$

$\vdash : \text{Hp} . \supset . \text{N}_0\text{c}`\rho = \text{sm}``\text{N}_0\text{c}`\sigma . \text{N}_0\text{c}`\sigma = \text{sm}``\text{N}_0\text{c}`\rho :$

[*120·152.*103·13] $\supset \vdash . \text{Prop}$

***120·21.** $\vdash : \rho \in \text{Cls induct} . \equiv . \text{N}_0\text{c}`\rho \in \text{NC induct}$

Dem.

$\vdash . *120·14·2 . \supset \vdash : \rho \in \text{Cls induct} . \equiv . (\exists \alpha) . \alpha \in \text{NC induct} . \alpha \in \text{NC} . \rho \in \alpha .$

[*103·27] $\equiv . (\exists \alpha) . \alpha \in \text{NC induct} . \text{N}_0\text{c}`\rho = \alpha .$

[*13·195] $\equiv . \text{N}_0\text{c}`\rho \in \text{NC induct} : \supset \vdash . \text{Prop}$

Note that "$\rho \in \text{Cls induct} . \equiv . \text{Nc}`\rho \in \text{NC induct}$" is not proved above. The proof encounters the difficulty that we may have $\text{Nc}`\rho = \Lambda$; in order to establish our proposition in this case, we have to show that if $\Lambda \in \text{NC induct}$, then *every* class is an inductive class. We can however prove the following implication.

***120·211.** $\vdash : \text{Nc}`\rho \in \text{NC induct} - \iota`\Lambda . \supset . \rho \in \text{Cls induct}$

Dem.

$\vdash . *100·511 . \supset \vdash : \text{Hp} . \supset . \text{sm}``\text{Nc}`\rho = \text{N}_0\text{c}`\rho .$

[*120·15] $\supset . \text{N}_0\text{c}`\rho \in \text{NC induct} .$

[*120·21] $\supset . \rho \in \text{Cls induct} : \supset \vdash . \text{Prop}$

***120·212.** $\vdash . \Lambda \in \text{Cls induct}$ [*120·211·12]

***120·213.** $\vdash . \iota`x \in \text{Cls induct}$ [*120·211·122]

***120·214.** $\vdash :. \rho \,\text{sm}\, \sigma . \supset : \rho \in \text{Cls induct} . \equiv . \sigma \in \text{Cls induct}$ [*120·201·21]

The following propositions are lemmas for *120·24.

***120·22.** $\vdash :: \eta \in \mu . \supset_{\eta, y} . \eta \cup \iota`y \in \mu : \Lambda \in \mu : \supset_\mu . \rho \in \mu :. \supset . \rho \in \text{Cls induct}$

Dem.

$\vdash . *120·212 . \supset \vdash . \Lambda \in \text{Cls induct}$ (1)

$\vdash . *51·2 . \supset \vdash :. y \in \eta . \supset : \eta \cup \iota`y = \eta :$

[*13·12] $\supset : \eta \in \text{Cls induct} . \supset . \eta \cup \iota`y \in \text{Cls induct}$ (2)

$\vdash . *110·63 . \supset \vdash :. y \sim\in \eta . \supset : \text{Nc}`(\eta \cup \iota`y) = \text{Nc}`\eta +_c 1$

[(*110·03)] $= \text{N}_0\text{c}`\eta +_c 1 :$

[*120·121] $\supset : \text{N}_0\text{c}`\eta \in \text{NC induct} . \supset . \text{N}_0\text{c}`(\eta \cup \iota`y) \in \text{NC induct} :$

[*120·21·211] $\supset : \eta \in \text{Cls induct} . \supset . \eta \cup \iota`y \in \text{Cls induct}$ (3)

$\vdash . (2) . (3) . \supset \vdash : \eta \in \text{Cls induct} . \supset . \eta \cup \iota`y \in \text{Cls induct}$ (4)

$\vdash . *10·1 . (1) . (4) . \supset \vdash . \text{Prop}$

***120·221.** $\vdash :. \eta \epsilon \mu . \supset_{\eta,y} . \eta \cup \iota{}^\backprime y \epsilon \mu : \mathrm{Nc}{}^\backprime\rho \subset \mu : \supset . \mathrm{Nc}{}^\backprime\rho +_0 1 \subset \mu$

Dem.

$\vdash . *110{\cdot}63 . *100{\cdot}31 . \supset$

$\vdash : \zeta \epsilon \mathrm{Nc}{}^\backprime\rho +_0 1 . \equiv . (\exists \eta, y) . \eta \epsilon \mathrm{Nc}{}^\backprime\rho . y \sim\epsilon \eta . \zeta = \eta \cup \iota{}^\backprime y$ (1)

This proposition might be used to define inductive classes. It gives a form of mathematical induction applicable to classes instead of to numbers. Virtually it states that an inductive class is one which can be formed by adding members one at a time, starting from Λ. This is made more explicit in *120·25. Instead of $\eta \epsilon \mu . \supset_{\eta,y} . \eta \cup \iota{}^\backprime y \epsilon \mu$, in the above propositions, as well as in those that follow, we may plainly substitute

$$\eta \epsilon \mu . y \sim\epsilon \eta . \supset_{\eta,y} . \eta \cup \iota{}^\backprime y \epsilon \mu .$$

The following definition, in which "spec" stands for "species," defines the "species" of a cardinal β as all cardinals which are less than, equal to, or greater than β. We cannot prove, unless by assuming the multiplicative axiom, that all cardinals belong to the species of β, except in the case where β is an inductive cardinal. In all other cases there may, so far as is known at present, be other cardinals which are neither greater nor less than β.

$*120 \cdot 492$. $\vdash : \alpha \in \mathrm{NC} - \mathrm{NC\,induct} \,.\, \beta \geqslant \alpha \,.\, \supset \,.\, \beta \in \mathrm{NC} - \mathrm{NC\,induct}$
[$*120 \cdot 48 \,.\, \mathrm{Transp}$]

In virtue of $*120 \cdot 491$, a class ξ which is not inductive contains sub-classes having 0, 1, 2, 3, ... terms. If we take the successive classes of sub-classes

$$0 \cap \mathrm{Cl}`\xi,\ 1 \cap \mathrm{Cl}`\xi,\ 2 \cap \mathrm{Cl}`\xi,\ \ldots,$$

these are mutually exclusive, and all exist provided Λ is not an inductive

cardinal, *i.e.* provided the axiom of infinity holds. Thus if the axiom of infinity holds, we get $\aleph_0$ classes of sub-classes contained in any non-inductive class. It follows, as we shall see later, that if ξ is a non-inductive class, $\text{Cl}`\text{Cl}`\xi$ is a reflexive class. This seems to be the nearest approach possible to identifying the two definitions of finite and infinite when the multiplicative axiom is not assumed. When the multiplicative axiom is assumed as well as the axiom of infinity, we pick out one class from $1 \cap \text{Cl}`\xi$, one from $2 \cap \text{Cl}`\xi$ and so on; then, forming the logical sum of all these classes, we get $\aleph_0$ terms which are members of ξ. Hence it follows that ξ is a reflexive class; for, as we shall see later, a reflexive class is one which contains sub-classes of $\aleph_0$ terms. Thus with the help of the multiplicative axiom, the two definitions of finite and infinite can be identified.

$*121$. INTERVALS

Summary of $*121$.

The present number is concerned with the class of terms between x and y with respect to some relation P, *i.e.* those terms which lie on a road from x to y on which any two consecutive terms have the relation P. Such a road may be called a P-road, and if zPw, the step from z to w may be called a P-step. In order that a P-road from x to y should exist, it is necessary and sufficient that we should have $xP_{po}y$. When this condition is fulfilled, there will in general be many P-roads from x to y. But if $P \in \mathrm{Cls} \to 1 \,.\, \sim(yP_{po}y)$, or if $P \in 1 \to \mathrm{Cls} \,.\, \sim(xP_{po}x)$, then at most one road leads from x to y. This follows from the propositions of $*96$. In virtue of those propositions, if $P \in \mathrm{Cls} \to 1 \,.\, \sim(yP_{po}y) \,.\, xP_{po}y$, P is $1 \to 1$ throughout the road from x to y, and this road forms an open series. The two other possibilities with a $\mathrm{Cls} \to 1$ are (assuming $xP_{po}y$)

$$(1)\ xP_{po}x,$$
$$(2)\ yP_{po}y \,.\, \sim(xP_{po}x).$$

In the first case, there is a cyclic road from x to x, and there are two roads from x to y, one consisting of that part of the cycle which is required to reach y, the other consisting of this part together with the whole cycle required to travel from y back to y. Thus the class of terms which can be reached in some journey from x to y is the whole class of descendants of x, *i.e.* the class $\overleftarrow{R}_*{}'x$, which is the cycle composing the road from x to x.

In the second case, the descendants of x form a Q, and y is in the circular part of the Q. Here, as before, there are two roads from x to y, of which the first stops as soon as it reaches y, while the second proceeds to travel round the circle until it comes to y again. Thus here again, all the descendants of x lie on some road between x and y.

The *interval* between x and y is defined as the class of terms lying on some road from x to y. There will be four kinds of interval, according as we do or do not include the end-points as such. We denote the kind including both end-points by

$$P(x \vdash\!\dashv y),$$

that excluding both by

$$P(x - y),$$

and the other two respectively by

$$P(x -\!\!\dashv y),\ P(x \vdash\!\!- y).$$

The definitions are

$$\overleftarrow{P}_*{}'x \cap \overrightarrow{P}_*{}'y,\ \overleftarrow{P}_{po}{}'x \cap \overrightarrow{P}_{po}{}'y,\ \overleftarrow{P}_{po}{}'x \cap \overrightarrow{P}_*{}'y,\ \overleftarrow{P}_*{}'x \cap \overrightarrow{P}_{po}{}'y.$$

If P is either one-many or many-one, it will be one-one throughout the interval $P(x \mapsto y)$, except at most at one exceptional point, namely the junction of the tail and circle of the Q. If $xP_{po}x$ or $\sim(yP_{po}y)$, the interval between x and y cannot be Q-shaped, but must be either open or cyclic; in either case, P is $1 \rightarrow 1$ throughout $P(x \mapsto y)$, with no exceptions; for if $P \epsilon \text{Cls} \rightarrow 1$, P is $1 \rightarrow 1$ throughout the interval because the interval is contained in $\overleftarrow{P_*}\text{‘}x$, and if $P \epsilon 1 \rightarrow \text{Cls}$, because the interval is contained in $\overrightarrow{P_*}\text{‘}y$. Thus throughout this number we shall constantly have the hypothesis $P \epsilon (\text{Cls} \rightarrow 1) \cup (1 \rightarrow \text{Cls})$; if $P \epsilon \text{Cls} \rightarrow 1$, the interval is to be supposed traversed from x to y, while if $P \epsilon 1 \rightarrow \text{Cls}$, it is to be supposed traversed from y to x. In either case the interval between x and y must be an *inductive* class. This is proved in $*121{\cdot}47$. If, however, P is serial (cf. $*204$), and thus neither many-one nor one-many, the interval between x and y is the stretch of the series between x and y, with or without end-points according to the definition chosen, and need not be an inductive class.

If the interval between x and y (both included) has $\nu +_c 1$ members, we say that $xP_\nu y$. Thus if there is only one road from x to y, "$xP_\nu y$" means that it requires ν steps to get from x to y. Assuming $P \epsilon \text{Cls} \rightarrow 1$, if we also have $P_{po} \subset J$ (*i.e.* if none of the families of P are cyclic), then if $xP_\nu y$ and yPz, we shall have $xP_{\nu +_c 1} z$. On this basis an inductive theory of P_ν is built up, and it is shown that the class of such relations as P_ν for different inductive values of ν is the same as Potid‘P, the class of powers of P including $I \restriction C\text{‘}P$ ($*121{\cdot}5$). The definition of P_ν is

$$P_\nu = \hat{x}\hat{y}\,\{\text{N}_0\text{c‘}P(x \mapsto y) = \nu +_c 1\} \quad \text{Df.}$$

The whole class of such relations as P_ν for different inductive values of ν is called finid‘P, *i.e.* we put

$$\text{finid‘}P = \hat{R}\,\{(\exists \nu) \,.\, \nu \,\epsilon\, \text{NC induct} - \iota\text{‘}\Lambda \,.\, R = P_\nu\} \quad \text{Df.}$$

If $B\text{‘}P$ exists, and if $P \epsilon \text{Cls} \rightarrow 1$, then the descendants of $B\text{‘}P$, so long as we do not reach a term y for which $yP_{po}y$, may be unambiguously described as the 2nd, 3rd, ... νth, ... terms of the posterity of $B\text{‘}P$, $B\text{‘}P$ itself being the 1st term. The correlation thus effected with the inductive cardinals is the logical essence of the process of counting; the last cardinal used in the correlation is the cardinal number of terms counted. We will call these terms $1_P, 2_P, \ldots \nu_P, \ldots$, defining ν_P as follows:

$$\nu_P = \breve{P}_{\nu -_c 1}\text{‘}B\text{‘}P \quad \text{Df.}$$

This notation does not conflict with ν_ξ as defined in $*65{\cdot}01$. There ξ must be a class if ν is a cardinal, here ν must be a cardinal and P a relation.

Hence whenever ν_P exists, the number of terms from the beginning to ν_P (both included) is ν. This is the fact upon which counting relies. If P is a many-one and P_{po} is contained in diversity, and ν is any inductive cardinal

other than 0, then ν_P exists when and only when $\overleftarrow{P_*}{}^{\text{\textquoteleft}}B{}^{\text{\textquoteleft}}P$ has at least ν members; *i.e.* roughly speaking, ν_P exists whenever it could possibly be expected to exist. In this case the whole posterity of $B{}^{\text{\textquoteleft}}P$ is contained in the series $1_P, 2_P, \dots \nu_P, \dots$ (*121·62). If the posterity is an inductive class, this series stops; if not, it forms a *progression* (cf. *122).

The propositions of the present number are very useful, not only in this section, but in the ordinal theory of finite and infinite and in parts of the book subsequent to that theory.

After some propositions which merely repeat definitions and give immediate consequences, we proceed (*121·3 ff.) to the theory of P_ν. We have

***121·302.** $\vdash : P_{\mathrm{po}} \in J . \supset . P_0 = I \upharpoonright C{}^{\text{\textquoteleft}}P$

***121·305.** $\vdash : P_{\mathrm{po}} \in J . \supset . P_1 \in P$

***121·31.** $\vdash : P \in (1 \to \mathrm{Cls}) \cup (\mathrm{Cls} \to 1) . P_{\mathrm{po}} \in J . \supset . P_1 = P$

When P is a transitive serial relation, we shall have $P_1 = P \dot{-} P^2$.

***121·321.** $\vdash : \nu > 0 . \supset . P_\nu \in P_{\mathrm{po}}$

***121·333.** $\vdash : P \in \mathrm{Cls} \to 1 . P_{\mathrm{po}} \in J . \supset . P_{\nu +_c 1} = P \mid P_\nu$

***121·35·351·352.** $\vdash : P \in (1 \to \mathrm{Cls}) \cup (\mathrm{Cls} \to 1) . P_{\mathrm{po}} \in J . \mu, \nu \in \mathrm{NC\,induct} . \supset .$
$$P_\mu \mid P_\nu = P_\nu \mid P_\mu = P_{\mu +_c \nu}$$

A similar result holds for $(P_\mu)_\nu$, which $= P_{\mu \times_c \nu}$ in the same circumstances.

We next proceed to the proof that an interval (under a similar hypothesis) is always an inductive class. This occupies *121·4—·47, being summed up in the proposition

***121·47.** $\vdash : R \in (\mathrm{Cls} \to 1) \cup (1 \to \mathrm{Cls}) . \supset . R(x \mapsto\!\dashv z) \in \mathrm{Cls\,induct}$

This is an important proposition. It leads to

***121·481.** $\vdash :. R \in \mathrm{Cls} \to 1 . \supset : \mathrm{Nc}{}^{\text{\textquoteleft}}R(x \mapsto\!\dashv y) \leqslant \mathrm{Nc}{}^{\text{\textquoteleft}}R(x \mapsto\!\dashv z) . \equiv .$
$$R(x \mapsto\!\dashv y) \subset R(x \mapsto\!\dashv z)$$
with a similar proposition if $R \in 1 \to \mathrm{Cls}$.

The next set of propositions (*121·5—·52) is concerned with $\mathrm{finid}{}^{\text{\textquoteleft}}P$. Assuming $P \in (\mathrm{Cls} \to 1) \cup (1 \to \mathrm{Cls}) . P_{\mathrm{po}} \in J$, we prove that $\mathrm{finid}{}^{\text{\textquoteleft}}P = \mathrm{Potid}{}^{\text{\textquoteleft}}P$ and $\mathrm{finid}{}^{\text{\textquoteleft}}P - \iota{}^{\text{\textquoteleft}}P_0 \subset \mathrm{Pot}{}^{\text{\textquoteleft}}P$ (*121·5); that if P is not null, $\mathrm{finid}{}^{\text{\textquoteleft}}P - \iota{}^{\text{\textquoteleft}}P_0 = \mathrm{Pot}{}^{\text{\textquoteleft}}P$ (*121·501); that $\dot{s}{}^{\text{\textquoteleft}}\mathrm{finid}{}^{\text{\textquoteleft}}P = P_*$ (*121·52) and $\dot{s}{}^{\text{\textquoteleft}}(\mathrm{finid}{}^{\text{\textquoteleft}}P - \iota{}^{\text{\textquoteleft}}P_0) = P_{\mathrm{po}}$ (*121·502); and that $P_2 = P^2 . P_3 = P^3 .$ etc. (*121·51).

Our next set of propositions is concerned with ν_P (*121·6—·638). We have

***121·601.** $\vdash : \mathrm{E}\,!\, B{}^{\text{\textquoteleft}}P . \supset . B{}^{\text{\textquoteleft}}P = 1_P . \sim \{(B{}^{\text{\textquoteleft}}P)\, P_{\mathrm{po}}\, (B{}^{\text{\textquoteleft}}P)\}$

***121·602.** $\vdash : \mathrm{E}\,!\, B{}^{\text{\textquoteleft}}P . P \in 1 \to 1 . \supset . \breve{P}{}^{\text{\textquoteleft}}B{}^{\text{\textquoteleft}}P = 2_P$

***121·634.** $\vdash :. P \in \mathrm{Cls} \to 1 . P_{\mathrm{po}} \in J . \nu \in \mathrm{NC\,induct} - \iota{}^{\text{\textquoteleft}}0 . \supset :$
$$\nu_P \in \mathrm{D}{}^{\text{\textquoteleft}}P . \equiv . \mathrm{E}\,!\,(\nu +_c 1)_P$$

Finally we have three propositions (∗121·7—·72) on $\overrightarrow{R_*}\text{‘}x$, of which the most useful is

∗121·7. $\vdash : R \in 1 \to 1 \,.\, aBR \,.\, aR_* x \,.\, \supset \,.\, \overrightarrow{R_*}\text{‘}x = R\,(a \mapsto x) \,.\, \overrightarrow{R_*}\text{‘}x \in \text{Cls induct}$

∗121·01. $P\,(x - y) = \overleftarrow{P_{\text{po}}}\text{‘}x \cap \overrightarrow{P_{\text{po}}}\text{‘}y$ Df

∗121·011. $P\,(x \dashv y) = \overleftarrow{P_{\text{po}}}\text{‘}x \cap \overrightarrow{P_*}\text{‘}y$ Df

∗121·012. $P\,(x \vdash y) = \overleftarrow{P_*}\text{‘}x \cap \overrightarrow{P_{\text{po}}}\text{‘}y$ Df

∗121·013. $P\,(x \mapsto y) = \overleftarrow{P_*}\text{‘}x \cap \overrightarrow{P_*}\text{‘}y$ Df

∗121·02. $P_\nu = \hat{x}\hat{y}\,\{\text{N}_0\text{c‘}P\,(x \mapsto y) = \nu +_{\text{c}} 1\}$ Df

$\vdash . (4) . (5) . (6) . \supset \vdash . \mathrm{Prop}$

The following series of propositions are concerned with proving $*121{\cdot}47$, *i.e.*

$$R \in (\mathrm{Cls} \to 1) \cup (1 \to \mathrm{Cls}) \,.\, \supset .\, R(x \vdash\!\dashv z) \in \mathrm{Cls\ induct.}$$

The proof for $R \in 1 \to \mathrm{Cls}$ follows from that for $R \in \mathrm{Cls} \to 1$ by $*121{\cdot}143$. Confining ourselves, therefore, to $R \in \mathrm{Cls} \to 1$, we proceed as follows.

We prove first that, starting from z and going backwards, each new step adds only one term (which may not be distinct from all its predecessors); *i.e.* we have

$$R \in \mathrm{Cls} \to 1 \,.\, xRy \,.\, yR_*z \,.\, \supset .\, R(x \vdash\!\dashv z) = \iota^{\backprime}x \cup R(y \vdash\!\dashv z).$$

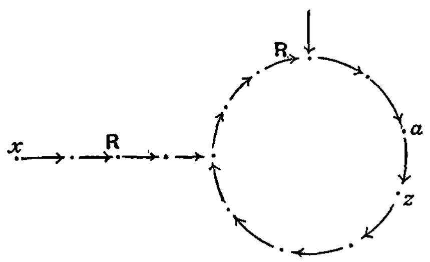
From this it follows by induction that if $R(z \vdash\!\dashv z)$ is an inductive class, so is $R(x \vdash\!\dashv z)$. Thus we only have to prove that $R(z \vdash\!\dashv z)$ is an inductive class. Here we must distinguish two cases, according as $\sim(zR_{\text{po}}z)$ or $zR_{\text{po}}z$. In the former case, we have

$$\exists ! R(z \vdash\!\dashv z) \,.\supset.\, R(z \vdash\!\dashv z) = \iota \text{`} z,$$

whence $R(z \vdash\!\dashv z)$ is an inductive class, and therefore so is $R(x \vdash\!\dashv z)$.

But in the latter case, when $zR_{\text{po}}z$, the matter is more difficult. In this case, z is a member of a cycle, the cycle being $R(z \vdash\!\dashv z)$. We have to prove that this cycle must be an inductive class. Given xR_*z, x will be a member of this cycle if $xR_{\text{po}}x$, and may be at the end of the tail of a Q, if $\sim(xR_{\text{po}}x)$. (Cf. $*96$.)

By $*96 \cdot 453$, we know that R is $1 \rightarrow 1$ when confined to $R(z \vdash\!\dashv z)$. Hence



in $R(z \vdash\!\dashv z)$, z has a unique predecessor, say a. Assume $a \neq z$. We then imagine a barrier placed between a and z, *i.e.* we construct a relation S which is to hold between any two consecutive members of $R(z \vdash\!\dashv z)$ except a and z. Putting $\alpha = R(z \vdash\!\dashv z) - \iota \text{`} a$, we have $S = \alpha \upharpoonleft R$. Then the relation S generates an *open* series consisting of all the terms of $R(z \vdash\!\dashv z)$; *i.e.* we have

$$\sim(aS_{\text{po}}a) \,.\, S(z \vdash\!\dashv a) = R(z \vdash\!\dashv z).$$

Hence, by our previous case, since $S(z \vdash\!\dashv a)$ is an inductive class, so is $R(z \vdash\!\dashv z)$.

If $a = z$, then by $*96 \cdot 33$ the cycle reduces to the single term z, and therefore $R(z \vdash\!\dashv z)$ is still an inductive class.

Hence $R(z \vdash\!\dashv z)$, and therefore $R(x \vdash\!\dashv z)$, is always an inductive class when $R \in \text{Cls} \rightarrow 1$, which was to be proved.

$*121 \cdot 4$. $\vdash : R \in \text{Cls} \rightarrow 1 \,.\, xRy \,.\, yR_*z \,.\supset.\, R(x \vdash\!\dashv z) = \iota \text{`} x \cup R(y \vdash\!\dashv z)$

$\vdash \,.\, (2) \,.\, (3) \,.\, \supset \vdash \,.\, \mathrm{Prop}$

In virtue of this proposition, we have only to prove $R(z \mapsto z) \epsilon \mathrm{Cls\ induct}$. This is obvious when $\sim(zR_{\mathrm{po}}z)$, for then either $R(z \mapsto z) = \iota`z$ or $R(z \mapsto z) = \Lambda$. But when $zR_{\mathrm{po}}z$, it is more difficult.

$[*121\cdot5 . *91\cdot55]$

We shall at a later stage ($*301$) give a general definition of P^ν. When this definition has been introduced, we shall be able to prove, with the hypothesis of $*121\cdot51$,
$$\nu \in \text{NC induct} . \supset . P_\nu = P^\nu.$$
The definition of P^ν is postponed on account of various complications which render a general definition of P^ν difficult. The chief difficulty arises when $\exists ! P \dot{\wedge} I$. Thus suppose we have yPy; we shall also have yP^2y, yP^3y, etc. Hence if we have xPy, we have
$$\nu \in \text{NC induct} - \iota`0 . \supset_\nu . xP^\nu y.$$
Again, suppose this case excluded, but suppose
$$(\exists \mu, y) . \mu \in \text{NC induct} . y \in P(x \mapsto z) . yP^\mu y.$$
Then we shall have
$$\nu \in \text{NC induct} - \iota`0 - \iota`\Lambda . \supset . yP^{\mu \times_c \nu} y.$$
Thus the general definition of P^ν has to be complicated, except when $P_{\text{po}} \subset J$.

The following propositions are concerned with the series of relations P_ν and the series of terms ν_P. The relation P_ν holds between two terms (roughly speaking) when it requires ν steps to get from the first to the second; the term ν_P is the νth term starting from $B`P$, which, when it exists, is $1_P$. In order that $\nu_P$ should exist, it is necessary that $B`P$ should exist, and that there should be just one term x in the field of P such that the interval from $B`P$ to $x$ (both included) consists of $\nu$ terms. When this is the case for all inductive cardinals from 1 to $\nu$, we can say that $P$ generates a series starting from $B`P$ and having at least ν terms, each correlated with one of the cardinals in the interval from 1 to ν, both included; *i.e.* the series has a μth term, whenever $1 \leqslant \mu \leqslant \nu$. If this holds for all inductive values of ν, the family of

$B‘P$ is a progression*. (It will be observed that all such terms as ν_P belong to the family of $B‘P$, which need not form the whole field of P.)

$*122$. PROGRESSIONS

Summary of $*122$.

By a "progression" we mean a series which is like the series of the inductive cardinals in order of magnitude (assuming that all inductive cardinals exist), *i.e.* a series whose terms can be called

$$1_R, 2_R, 3_R, \ldots \nu_R, \ldots,$$

where every term of the series is correlated with some inductive cardinal, and every inductive cardinal is correlated with some term of the series. Such series belong to the relation-number (cf. $*152$ and $*263$) which Cantor calls ω. Their generating relation may be taken to be the transitive relation of earlier and later, or the one-one relation of immediate predecessor to immediate successor. We shall reserve the notation ω for the *transitive* generating relations of progressions; for the present, we are concerned with the one-one relations which generate progressions. The class of these relations we shall call "Prog."

It is not convenient to *define* a progression as a series which is ordinally similar to that of the inductive cardinals, both because this definition only applies if we assume the axiom of infinity, and because we have in any case to show that (assuming the axiom of infinity) the series of inductive cardinals has certain properties, which can be used to afford a direct definition of progressions. The existence of progressions, however, is only obtainable by means of the axiom of infinity, and is then most easily obtained from the fact that the inductive cardinals form a progression. We shall not consider the existence-theorem until the next number ($*123$).

From this number onwards convention Infin T of the Prefatory Statement is used when relevant.

The characteristics of the generating relation R of a progression, which we employ in the definition, are the following:

(1) R is a one-one relation;

(2) there is a first term, *i.e.* $\mathrm{E} \,!\, B\text{'}R$;

(3) the whole field is contained in the posterity of the first term, *i.e.* $C\text{'}R = \overleftarrow{R_*}\text{'}B\text{'}R$. (If this failed, $C\text{'}R$ would consist of two or more distinct families, of which, since we have $\mathrm{E} \,!\, B\text{'}R$, all but one would have to be cyclic families or infinite families with neither beginning nor end.)

(4) every term of the field has a successor, *i.e.* the series is endless. This is secured by $\text{Cl}\text{'}R \subset \mathrm{D}\text{'}R$, or (what is equivalent) $C\text{'}R = \mathrm{D}\text{'}R$.

These four properties suffice to define the one-one generating relations of progressions. It will be observed that (2), (3) and (4) are all secured by

$$\text{D}`R = \overleftarrow{R_*}`B`R.$$

This secures $\text{E} ! B`R$, by *14·21; it secures $\text{Ꭰ}`R \subset \text{D}`R$, by *37·25 and *90·163; hence, by *33·181, $\text{D}`R = C`R$, and therefore

$$C`R = \overleftarrow{R_*}`B`R.$$

Hence our definition of progressions is

$$\text{Prog} = (1 \to 1) \cap \hat{R}\,(\text{D}`R = \overleftarrow{R_*}`B`R) \quad \text{Df.}$$

Instead of stating in the definition that R is to be a one-one relation, it is sufficient to put $R \in \text{Cls} \to 1 \,.\, R_{\text{po}} \subseteq J$, which, with $\text{D}`R = \overleftarrow{R_*}`B`R$, implies $R \in 1 \to 1$, and may be substituted for $R \in 1 \to 1$ without altering the force of the definition (*122·17).

In the present number we shall prove, among other propositions, that every existent class contained in a progression has a first term (*122·23), *i.e.* that progressions are well-ordered series; that in a progression $R_{\text{po}} \subseteq J$ (*122·16), which makes the propositions of *121 available; that if ν is any inductive cardinal other than 0, ν_R exists (*122·33), *i.e.* the series has a νth term; that any class contained in $\text{D}`R$ and having a last term is an inductive class (*122·43), and that any class contained in $\text{D}`R$ and not having a last term is itself the domain of a progression (*122·45), so that every class contained in $\text{D}`R$ is either inductive or the domain of a progression (*122·46); that if P is a many-one, and x a member of its domain, and if the descendants of x have no last term and are none of them descendants of themselves, then P arranges these descendants in a progression (*122·51); and that the same holds if P is a one-one and $\sim(xPx)$ (*122·52); and that if $P \in 1 \to 1$ and x belongs to one of the generations of P, but not to one of the generations of $\breve{P}$, then P arranges the whole family of x in a progression (*122·54).

The following general observations on the families of one-one relations may serve to elucidate the bearing of the propositions of this section.

Given any relation P, we call $\overleftrightarrow{P_*}`x$, *i.e.* $\overrightarrow{P_*}`x \cup \overleftarrow{P_*}`x$, the *family* of x. If P is a one-one, this family may be of four different kinds. (1) It may be a closed series, like the angles of a polygon. This occurs if $xP_{\text{po}}x$. In this case the family forms an inductive class. (2) It may be an open series with a beginning and an end; this occurs if

$$\sim(xP_{\text{po}}x) \,.\, \text{E} ! \min_P`\overleftrightarrow{P_*}`x \,.\, \text{E} ! \max_P`\overleftrightarrow{P_*}`x.$$

In this case also the family forms an inductive class. (3) It may be an

open series with a beginning and no end, or an end and no beginning. This occurs if

$$\sim(xP_{po}x) \,.\, \text{E}\,!\,\text{min}_P`\overleftrightarrow{P}_*`x \,.\, \sim\text{E}\,!\,\text{max}_P`\overleftrightarrow{P}_*`x,$$

or if

$$\sim(xP_{po}x) \,.\, \sim\text{E}\,!\,\text{min}_P`\overleftrightarrow{P}_*`x \,.\, \text{E}\,!\,\text{max}_P`\overleftrightarrow{P}_*`x.$$

In this case, the series is of the type ω or $\text{Cnv}``\omega$, and is non-inductive and reflexive. (4) The series may be open and have neither beginning nor end. This occurs if

$$\sim(xP_{po}x) \,.\, \sim\text{E}\,!\,\text{min}_P`\overleftrightarrow{P}_*`x \,.\, \sim\text{E}\,!\,\text{max}_P`\overleftrightarrow{P}_*`x.$$

In this case we get a series whose relation-number is the sum (in the sense of $*180$) of $\text{Cnv}``\omega$ and ω, which again is non-inductive and reflexive. In all four cases, if y and z be any two members of the family of x, the interval between y ana z is an inductive class.

If x is a member of $\overrightarrow{B}`P$, or if the family of $x$ contains a member of $\overrightarrow{B}`P$, cases (1) and (4) are excluded, since the series has a beginning. In this case the number of predecessors of any term is an inductive number. It will be observed that every family is either wholly contained in $s`\text{gen}`P$ or wholly contained in $p`\text{Cl}``\text{Pot}`P$; families of kinds (2) and (3) (excluding, in (2), those which have an end but no beginning) are contained in $s`\text{gen}`P$, while families of kinds (1) and (4), and those of (2) which have an end but no beginning, are contained in $p`\text{Cl}``\text{Pot}`P$; families containing a member of $\overrightarrow{B}`P$ are contained in $s`\text{gen}`P$, while all others are contained in $p`\text{Cl}``\text{Pot}`P$.

Thus a one-one relation in general gives rise to a number of wholly disconnected series, some closed, others open and with or without a beginning or an end. The condition that all the series should be open is $P_{po} \subset J$.

The case of a Q-shaped family, considered in $*96$, cannot arise when $P \in 1 \rightarrow 1$, for in a Q-shaped family the term at the junction of the tail and the circle has two predecessors, one in the tail and one in the circle, so that the relation in question is not $1 \rightarrow 1$. It follows that, when $P \in 1 \rightarrow 1$, if α is a family containing a member of $\overrightarrow{B}`P$, $\alpha \rceil P_{po} \subset J$ (cf. $*96{\cdot}23$).

When $B`P$ exists, there is only one family which has a beginning. In this case, ignoring the other families (if any), we call the members of the family of $B`P$ respectively 1_P, 2_P, 3_P, ... If the family has ν members, where ν is an inductive cardinal, its last member will be ν_P. If on the other hand the number of members of the family is not an inductive cardinal, it must be $\aleph_0$; in this case, the family forms a progression, whose members are 1_P, 2_P, 3_P, ..., ν_P, ..., where ν_P always exists when ν is an inductive cardinal.

In addition to the propositions already mentioned, the following are important:

$*122\cdot21$. $\vdash :. R \in \text{Prog} . x, y \in C\text{'}R . \supset : x R_{\text{po}} y . \vee . x = y . \vee . y R_{\text{po}} x$

(Cf. note to $*122\cdot21$, below.)

$*122\cdot34$. $\vdash :. R \in \text{Prog} . \supset : \nu \in \text{NC induct} - \iota\text{'}0 . \equiv . \text{E} ! \nu_R$

$*122\cdot341$. $\vdash : R \in \text{Prog} . \supset . \text{D'}R = \hat{x}\{(\exists \nu) . \nu \in \text{NC induct} - \iota\text{'}0 . x = \nu_R\}$

In virtue of these two propositions, the terms of a progression are

$$1_R, 2_R, 3_R, \ldots \nu_R, \ldots,$$

where every inductive cardinal occurs. This is the same fact as is usually assumed when the terms are represented as

$$x_1, x_2, x_3, \ldots x_\nu, \ldots.$$

$*122\cdot35$. $\vdash : R \in \text{Prog} . \nu \in \text{NC induct} - \iota\text{'}0 . \supset . \overrightarrow{B}\text{'}R_\nu = R(1_R \mapsto \nu_R) . \overrightarrow{B}\text{'}R_\nu \in \nu$

$*122\cdot36$. $\vdash : \exists ! \text{Prog} \cap t^{11}\text{'}x . \supset . \text{Infin ax}(x)$

$*122\cdot37$. $\vdash : R \in \text{Prog} . \supset . \text{D'}R \sim\in \text{Cls induct} . \text{N}_0\text{c'D'}R \sim\in \text{NC induct}$

$*122\cdot38$. $\vdash : R \in \text{Prog} . \supset . \overrightarrow{R_*}\text{'}x \in \text{Cls induct}$

I.e. the number of terms up to any given point of a progression is inductive.

$*122\cdot01$. $\text{Prog} = (1 \rightarrow 1) \cap \hat{R}(\text{D'}R = \overleftarrow{R_*}\text{'}B\text{'}R)$ Df

$*122\cdot1$. $\vdash : R \in \text{Prog} . \equiv . R \in 1 \rightarrow 1 . \text{D'}R = \overleftarrow{R_*}\text{'}B\text{'}R$ [$(*122\cdot01)$]

$*122\cdot11$. $\vdash :. R \in \text{Prog} . \equiv : R \in 1 \rightarrow 1 . \text{E} ! B\text{'}R : x \in \text{D'}R . \equiv_x . x \in \overleftarrow{R_*}\text{'}B\text{'}R$

Dem.

$\vdash . *122\cdot1 . *14\cdot205 . \supset$

$\vdash :: R \in \text{Prog} . \equiv :. R \in 1 \rightarrow 1 : (\exists a) . a = B\text{'}R . \text{D'}R = \overleftarrow{R_*}\text{'}a :.$

$[*20\cdot43]$ $\equiv :. R \in 1 \rightarrow 1 :. (\exists a) : a = B\text{'}R : x \in \text{D'}R . \equiv_x . x \in \overleftarrow{R_*}\text{'}a :.$

$[*14\cdot15]$ $\equiv :. R \in 1 \rightarrow 1 :. (\exists a) : a = B\text{'}R : x \in \text{D'}R . \equiv_x . x \in \overleftarrow{R_*}\text{'}B\text{'}R :.$

$[*14\cdot204]$ $\equiv :. R \in 1 \rightarrow 1 . \text{E} ! B\text{'}R : x \in \text{D'}R . \equiv_x . x \in \overleftarrow{R_*}\text{'}B\text{'}R :: \supset \vdash . \text{Prop}$

Observe that, by the conventions as to descriptive symbols, $\text{D'}R = \overleftarrow{R_*}\text{'}B\text{'}R$ involves the existence of $B\text{'}R$, whereas $x \in \text{D'}R . \equiv_x . x \in \overleftarrow{R_*}\text{'}B\text{'}R$ does not, since, if $B\text{'}R$ does not exist, we have $(x) . x \sim\in \overleftarrow{R_*}\text{'}B\text{'}R$, and therefore $(x) . x \sim\in \text{D'}R$ will satisfy the equivalence, *i.e.* Λ will satisfy the equivalence although it has no first term. This is the reason why $\text{E} ! B\text{'}R$ appears explicitly in $*122\cdot11$, though it was only implicit in $*122\cdot1$.

$*122\cdot12$. $\vdash :: R \in \text{Prog} . \equiv :. R \in 1 \rightarrow 1 . \text{E} ! B\text{'}R :. x \in \text{D'}R . \equiv_x :$

$\vdash . (3) . *122·1·16 . \supset \vdash . \mathrm{Prop}$

To illustrate this proposition, consider its application to the inductive cardinals arranged in order of magnitude; *i.e.* take as a value of R the relation

$$\hat{\mu}\hat{\nu}(\mu \epsilon \mathrm{NC\,induct} \,.\, \nu = \mu +_c 1).$$

We then have $R \epsilon \mathrm{Cls} \to 1 \,.\, 0 = B'R$; also

$$\mathrm{NC\,induct} = \mathrm{D}'R = \overleftarrow{R_*}'B'R.$$

We have also

$$\exists \,!\, \mu +_c 1 \,.\, \mu +_c 1 = \nu +_c 1 \,.\, \supset .\, \mu = \nu,$$

so that $$R \upharpoonright (-\iota'\Lambda) \epsilon 1 \to \mathrm{Cls}.$$

Again

$$\mu R_{\mathrm{po}} \nu \,.\, \equiv .\, (\exists \varpi) \,.\, \varpi \epsilon \mathrm{NC\,induct} - \iota'0 \,.\, \nu = \mu +_c \varpi,$$

whence $$\mu R_{\mathrm{po}} \nu \,.\, \exists \,!\, \mu \,.\, \supset .\, \mu \neq \nu,$$

i.e. $$(-\iota'\Lambda) \upharpoonleft R_{\mathrm{po}} \subseteq J.$$

But we do not get $R \epsilon 1 \to \mathrm{Cls}$ or $R_{\mathrm{po}} \subseteq J$ unless we have

$$\Lambda \sim\epsilon \mathrm{NC\,induct},$$

which is the axiom of infinity. If this condition fails, we reach at last an inductive cardinal which $= \Lambda$, and we have

$$\Lambda = \Lambda +_c 1,$$

so that Λ has two immediate predecessors, namely itself and the last existent cardinal. The posterity of 0, in this case, is a Q in which the circle has narrowed to a single term, namely Λ.

Thus we need the axiom of infinity in order to prove

$$\hat{\mu}\hat{\nu}(\mu \epsilon \mathrm{NC\,induct} \,.\, \nu = \mu +_c 1) \epsilon \mathrm{Prog}.$$

***122·2.** $\vdash :. R \epsilon \mathrm{Prog} \,.\, x, y \epsilon C'R \,.\, \supset : xR_*y \,.\, \vee \,.\, yR_*x$ [*96·302 . *122·1·141]

[*121·7 . *122·35]

The following series of propositions are concerned in proving that any class contained in a progression is inductive if it has a last term, and is a progression if it has no last term. In the latter case, it is supposed arranged in the same order as it had in the original progression. A certain complication is necessary in order to define its one-one generating relation. If R is the generating relation of the original progression, we proceed first to R_{po}, then to $R_{\text{po}} \upharpoonright \alpha$, where α is the class in question; this gives us a transitive generating relation for α. Calling this relation P, we then proceed to $P \dot{-} P^2$, *i.e.* the relation of consecutive members of the series generated by P. This relation turns out to be one-one, and to arrange α in a progression; hence our proposition is proved. The reason for the necessity of this detour is that consecutive members of α may not be consecutive members of the original progression.

∗122·41. $\vdash : R \in \text{Prog} . \alpha \subset \text{D}'R . y \in \alpha - R_{\text{po}}``\alpha . \supset . \alpha \subset R(B'R \mapsto y)$

Dem.

$\vdash . ∗37·1 . ∗10·51 . \supset \vdash :. \text{Hp} . \supset : z \in \alpha . \supset_z . \sim(yR_{\text{po}}z) .$

$[∗122·21] \qquad \supset_z . zR_*y \qquad (1)$

$\vdash . ∗122·1 . \qquad \supset \vdash :. \text{Hp} . \supset : z \in \alpha . \supset_z . (B'R) R_* z \qquad (2)$

$\vdash . (1) . (2) . ∗121·103 . \supset \vdash . \text{Prop}$

∗122·42. $\vdash : R \in \text{Prog} . \alpha \subset R(B'R \mapsto y) . y \in \alpha . \supset . y = \max_R{}'\alpha$

Dem.

$\vdash . ∗121·103 . \supset \vdash :. \text{Hp} . \supset : z \in \alpha . \supset_z . zR_*y .$

$[∗91·574.∗122·16] \qquad \supset_z . \sim(yR_{\text{po}}z) :$

$[∗37·1.∗10·51] \qquad \supset : y \sim\in R_{\text{po}}``\alpha : \qquad (1)$

$[∗96·303] \qquad \supset : z \in \alpha - R_{\text{po}}``\alpha . \supset_z . z = y \qquad (2)$

$\vdash . (1) . (2) . ∗93·115 . \supset \vdash . \text{Prop}$

∗122·43. $\vdash : R \in \text{Prog} . \alpha \subset \text{D}'R . \exists ! \alpha - R_{\text{po}}``\alpha . \supset . \alpha \in \text{Cls induct}$

$[∗122·41 . ∗121·45 . ∗120·481]$

Thus every class which is contained in a progression and has a last term is inductive. We have next to prove

$$R \in \text{Prog} . \alpha \subset \text{D}'R . \exists ! \alpha . \sim\exists ! \alpha - R_{\text{po}}``\alpha . \supset . \alpha \in \text{D}``\text{Prog}.$$

This is effected in the following propositions.

∗122·44. $\vdash : R \in \text{Prog} . \alpha \subset R_{\text{po}}``\alpha . \exists ! \alpha . P = R_{\text{po}} \upharpoonright \alpha . Q = P \dot{-} P^2 . \supset .$
$Q \in 1 \to 1 . Q \subseteq R_{\text{po}}$

Note. The hypothesis here exceeds what is necessary for the conclusion, but is the hypothesis required for ∗122·45, for which the present and the following propositions are lemmas.

$*123.\ \aleph_0$

Summary of $*123$.

In this number we are concerned with the arithmetical properties of $\aleph_0$, the smallest of Cantor's transfinite cardinals. Cantor defines $\aleph_0$ as the cardinal number of any class which can be put into one-one relation with the inductive cardinals. This definition assumes that $\nu \neq \nu +_c 1$, when ν is an inductive cardinal; in other words, it assumes the axiom of infinity; for without this, the inductive cardinals would form a finite series, with a last term, namely Λ. For this reason among others, we do not make similarity with the inductive cardinals our *definition*. We define $\aleph_0$ as the class of those classes which can be arranged in progressions, *i.e.* as $\mathrm{D}``\mathrm{Prog}$. We then have to prove that $\aleph_0$ so defined is a cardinal, and that if it is not null, it is the number of the inductive numbers.

For convenience we put for the moment N for the relation of μ to $\mu +_c 1$ when μ is an inductive cardinal. We then easily prove

$*123{\cdot}21{\cdot}23$. $\vdash . N \in \mathrm{Cls} \to 1 . \mathrm{D}`N = \mathrm{NC\,induct} . B`N = 0 . \overleftarrow{N_*}`0 = \mathrm{NC\,induct}$

The only thing further required to prove $N \in \mathrm{Prog}$ is $N \in 1 \to \mathrm{Cls}$, *i.e.*

$$\mu, \nu \in \mathrm{NC\,induct} . \mu +_c 1 = \nu +_c 1 . \supset . \mu = \nu.$$

By $*120{\cdot}311$, this holds if $\exists ! \mu +_c 1$, which holds if Infin ax holds. Hence

$*123{\cdot}25{\cdot}26$. $\vdash : \mathrm{Infin\,ax}(x) . \supset . N \upharpoonright t^3`x \in \mathrm{Prog} . \mathrm{NC\,induct} \cap t^3`x \in \aleph_0$

whence, by $*122{\cdot}36$,

$*123{\cdot}27$. $\vdash : \exists ! \aleph_0(x) . \supset . \mathrm{NC\,induct} \cap t^3`x \in \aleph_0$

Again it is obvious from $*122{\cdot}34{\cdot}341$ that if R is a progression, $\mathrm{D}`R$ can always be put into a $1 \to 1$ relation to the inductive cardinals ($*123{\cdot}3$) since $\mathrm{D}`R$ consists of the terms $1_R, 2_R, \ldots \nu_R, \ldots$, and all the inductive cardinals are used in putting $\mathrm{D}`R$ into this form. Hence

$*123{\cdot}31$. $\vdash : \alpha \in \aleph_0 . \supset . \alpha\ \mathrm{sm\ NC\,induct}$

whence also

$*123{\cdot}311$. $\vdash : \alpha, \beta \in \aleph_0 . \supset . \alpha\ \mathrm{sm}\ \beta$

It remains to prove that any class similar to the inductive cardinals is an $\aleph_0$; this can only be proved by assuming the axiom of infinity. We prove

first (*123·32) that if R is a progression, and S is a one-one whose converse domain is $\text{D}'R$, then $S \mid R \mid \breve{S}$ is a progression whose domain is $\text{D}'S$. Hence

***123·321.** $\vdash : \alpha \in \aleph_0 \,.\, \alpha \operatorname{sm} \beta \,.\, \supset .\, \beta \in \aleph_0$

From this and $\alpha, \beta \in \aleph_0 \,.\, \supset .\, \alpha \operatorname{sm} \beta$, we obtain

***123·322.** $\vdash : \alpha \in \aleph_0 \,.\, \supset .\, \aleph_0 = \text{Nc}'\alpha$

Hence by our previous results

***123·34.** $\vdash : \text{Infin ax}\,(x) \,.\, \supset .\, \aleph_0 = \text{Nc}'(\text{NC induct} \cap t^{3}{}'x)$

Also we have, by *123·322 above,

$$\exists ! \aleph_0 \,.\, \supset .\, \aleph_0 \in \text{NC},$$

whence, since $\Lambda \in \text{NC}$, we obtain at last

***123·36.** $\vdash .\, \aleph_0 \in \text{NC}$

As to the existence of $\aleph_0$ in various types, if $\text{Infin ax}\,(x)$ holds, *i.e.* if, given any inductive cardinal ν, there are classes having ν terms and composed of terms of the same type as x, then $\text{NC induct}\,(t'x) \in \aleph_0\,(t^2{}'x)$. Thus

***123·37.** $\vdash : \text{Infin ax}\,(x) \,.\, \supset .\, \exists ! \aleph_0\,(t^2{}'x) \,.\, \aleph_0\,(t^2{}'x) \in \text{N}_0\text{C}$

The arithmetical properties of $\aleph_0$ in regard to addition, multiplication and exponentiation by an inductive cardinal are easily proved. We have

***123·41.** $\vdash : \nu \in \text{NC induct} \,.\, \supset .\, \aleph_0 = \aleph_0 +_c \nu$

***123·421.** $\vdash .\, \aleph_0 = \aleph_0 +_c \aleph_0 = 2 \times_c \aleph_0$

***123·422.** $\vdash : \nu \in \text{NC induct} - \iota'0 \,.\, \supset .\, \nu \times_c \aleph_0 = \aleph_0$

***123·52.** $\vdash .\, \aleph_0 = \aleph_0 \times_c \aleph_0 = \aleph_0{}^2$

***123·53.** $\vdash : \nu \in \text{NC induct} - \iota'0 \,.\, \supset .\, \aleph_0{}^\nu = \aleph_0$

All these propositions are well known.

The early propositions of the present number are for the most part immediate consequences of propositions proved in *122.

$*124$. REFLEXIVE CLASSES AND CARDINALS

Summary of $*124$.

In this number, we have to take up the second definition of infinity mentioned in the introduction to this Section. A class which is infinite according to this definition we propose to call a reflexive class, because a class which is of this kind is capable of *reflexion* into a part of itself. A class is called *reflexive* when there is a one-one relation which correlates the class with a proper part of itself. (A *proper part* is a part not the whole.) A reflexive cardinal is the homogeneous cardinal of a reflexive class.

We prove easily that reflexive classes are not inductive ($*124{\cdot}271$), that reflexive cardinals are such as are greater than or equal to $\aleph_0$ ($*124{\cdot}23$), and such as are unchanged by adding 1 (excepting Λ) ($*124{\cdot}25$). To prove that classes which are not inductive must be reflexive has not hitherto been found possible without assuming the multiplicative axiom. We do not need, however, to assume the axiom generally, but only as applied to products of $\aleph_0$ factors. With this assumption, the result follows by a series of propositions explained below. Thus if a product of $\aleph_0$ factors, no one of which is zero, is never zero, then the two definitions of the finite and the infinite coincide ($*124{\cdot}56$).

We will call a cardinal ν a "multiplicative cardinal" if a product of ν factors none of which is zero is never zero. Thus all inductive cardinals are multiplicative cardinals; and the assumption needed for identifying the two definitions of finite and infinite is that $\aleph_0$ should be a multiplicative cardinal.

For a reflexive class we use the notation "Cls refl," and for a reflexive cardinal we use "NC refl." We define a reflexive cardinal as the *homogeneous* cardinal of a reflexive class, *i.e.* we put

$$\mathrm{NC\,refl} = \mathrm{N_0c}``\mathrm{Cls\,refl} \quad \mathrm{Df.}$$

The only effect of this is to exclude Λ from reflexive cardinals, which is convenient. We then need (on the analogy of $*110{\cdot}03{\cdot}04$) a definition of what is meant when an ambiguous symbol such as $\mathrm{Nc}`\alpha$ is said to be reflexive, and we therefore put

$$\mathrm{Nc}`\rho \in \mathrm{NC\,refl} \,.=.\, \mathrm{N_0c}`\rho \in \mathrm{NC\,refl} \quad \mathrm{Df.}$$

For the class of multiplicative cardinals we use the notation "NC mult." Thus we put

$$\mathrm{NC\,mult} = \mathrm{NC} \cap \hat{\alpha}\{\kappa \in \alpha \cap \mathrm{Cls\,ex^2\,excl} \,.\supset_\kappa .\, \exists ! \,\epsilon_\Delta`\kappa\} \quad \mathrm{Df,}$$

whence it follows that if $\alpha \in \mathrm{NC\,mult}$, a product of α factors, none of which is zero, will never be zero.

We begin, in this number, with the more obvious properties of Cls refl, proving that a Cls refl is one which contains sub-classes of $\aleph_0$ terms ($*124{\cdot}15$), that it is one whose number is unchanged when a single term is taken away ($*124{\cdot}17$), and that it remains reflexive if any inductive class is taken away from it ($*124{\cdot}182$).

We then give corresponding propositions concerning NC refl ($*124{\cdot}23{\cdot}25$ $\cdot 252$), proving, in addition to propositions already mentioned, that a reflexive cardinal is greater than every inductive cardinal ($*124{\cdot}26$), and that a class which is neither inductive nor reflexive (if there be such) is one which neither contains nor is contained in any progression ($*124{\cdot}34$). On such classes, see the remarks at the end of this number.

We then ($*124{\cdot}4{\cdot}41$) give a proposition merely embodying the definition of NC mult, and show that all inductive cardinals are multiplicative, which follows immediately from $*120{\cdot}62$.

The following series of propositions ($*124{\cdot}51$ ff.) are concerned with the proof that, if $\aleph_0$ is a multiplicative cardinal, then the two definitions of finite and infinite coalesce. The proof, which is somewhat complicated, proceeds as follows.

To begin with, we know that if ρ is a class which is not inductive, it contains classes having ν terms, if ν is any inductive cardinal. Thus we have

$$\exists ! 0 \cap \mathrm{Cl}`\rho, \ \exists ! 1 \cap \mathrm{Cl}`\rho, \ \ldots \ \exists ! \nu \cap \mathrm{Cl}`\rho, \ \ldots.$$

The classes of classes $0 \cap \mathrm{Cl}`\rho$, $1 \cap \mathrm{Cl}`\rho$, ... $\nu \cap \mathrm{Cl}`\rho$, ... thus form a progression, which is contained in $\mathrm{Cl}`\mathrm{Cl}`\rho$. Hence ($*124{\cdot}511$)

$$\vdash : \rho \sim \in \mathrm{Cls\,induct} \,.\supset .\, \mathrm{Cl}`\mathrm{Cl}`\rho \in \mathrm{Cls\,refl}.$$

So far, the multiplicative axiom is not required.

The above progression of classes of classes is

$$(\cap \mathrm{Cl}`\rho)``\mathrm{NC\,induct}.$$

If P is a selective relation for this class of classes, $\mathrm{D}`P$ is a progression contained in $\mathrm{Cl}`\rho$. Hence

$*124{\cdot}513$. $\vdash : \exists ! \epsilon_\Delta`(\cap \mathrm{Cl}`\rho)``\mathrm{NC\,induct} \,.\supset .\, \mathrm{Cl}`\rho \in \mathrm{Cls\,refl}$

whence

$*124{\cdot}514$. $\vdash :. \aleph_0 \in \mathrm{NC\,mult} \,.\supset :\, \rho \sim \in \mathrm{Cls\,induct} \,.\supset .\, \mathrm{Cl}`\rho \in \mathrm{Cls\,refl}$

To prove the next step, namely

$$\aleph_0 \in \mathrm{NC\,mult} \,.\, \exists ! \aleph_0 \cap \mathrm{Cl}`\mathrm{Cl}`\rho \,.\supset .\, \exists ! \aleph_0 \cap \mathrm{Cl}`\rho,$$

we make a fresh start. We have, by hypothesis, a progression R whose domain is contained in $\mathrm{Cl}`\rho$; hence $s`\mathrm{D}`R \subset \rho$. Thus it will suffice to prove

$$\aleph_0 \in \mathrm{NC\,mult} \,.\, R \in \mathrm{Prog} \,.\, \mathrm{D}`R \subset \mathrm{Cls\,induct} \,.\supset .\, \exists ! \aleph_0 \cap s`\mathrm{D}`R,$$

where the conditions of significance require that $\mathrm{D}`R$ should consist of classes.

For this purpose, we prove that no member of D‘R can be the last that has new members which have not occurred before. The proof proceeds by showing that if this were not so, s‘D‘R would be an inductive class, and therefore, by *120·75, D‘R would be an inductive class. Hence (*124·534) the members of D‘R which introduce new terms form an $\aleph_0$, by *123·19; and so therefore do the classes of new terms which they introduce (*124·535). Hence (*124·536) a selection from these classes of new terms, which is a subclass of s‘D‘R, is also an $\aleph_0$, and therefore (*124·54) there is a progression contained in s‘D‘R if the selection in question exists. This completes the proof.

In virtue of *124·511 and *120·74, we have, without the multiplicative axiom,

***124·6.** $\vdash : \rho \sim \epsilon \text{ Cls induct} . \equiv . \text{Cl‘Cl‘}\rho \,\epsilon \text{ Cls refl}$

Hence if it could be shown that Cl‘ρ cannot be reflexive unless ρ is reflexive, a double application of this would enable us, by means of *124·6, to identify the two definitions of the finite without the multiplicative axiom.

***124·01.** $\text{Cls refl} = \hat{\rho}\{(\exists R) . R \,\epsilon\, 1 \rightarrow 1 . \text{Cl‘}R \subset \text{D‘}R . \exists ! \overrightarrow{B}\text{‘}R . \rho = \text{D‘}R\}$ Df

An equivalent definition would be

$$\text{Cls refl} = \text{D“}\{(1 \rightarrow 1) \cap \text{Cl‘}B - \text{Cnv“Cl‘}B\} \quad \text{Df.}$$

***124·02.** $\text{NC refl} = \text{N}_0\text{c“Cls refl}$ Df

***124·021.** $\text{Nc‘}\rho \,\epsilon\, \text{NC refl} . = . \text{N}_0\text{c‘}\rho \,\epsilon\, \text{NC refl}$ Df

***124·03.** $\text{NC mult} = \text{NC} \cap \hat{\alpha}\{\kappa \,\epsilon\, \alpha \cap \text{Cls ex}^2 \text{ excl} . \supset_\kappa . \exists ! \epsilon_\Delta\text{‘}\kappa\}$ Df

***124·1.** $\vdash : \rho \,\epsilon\, \text{Cls refl} . \equiv . (\exists R) . R \,\epsilon\, 1 \rightarrow 1 . \text{Cl‘}R \subset \text{D‘}R . \exists ! \overrightarrow{B}\text{‘}R . \rho = \text{D‘}R$ [(*124·01)]

[$*124{\cdot}511{\cdot}513{\cdot}4$]

The following propositions are concerned in proving that, if $\aleph_0$ is a multiplicative cardinal, then a class such as $\mathrm{D}`P$ in $*124{\cdot}512$ must be such

that a progression is contained in s'D'P. The characteristics of D'P which are used in the proof are D'$P \epsilon \aleph_0$. D'$P \subset$ Cls induct. Since D'$P \epsilon \aleph_0$, we have $(\exists R) . R \epsilon \text{Prog} . \text{D}`P = \text{D}`R$. Hence the hypothesis with which the following series of propositions is concerned is

$$R \epsilon \text{Prog} . \text{D}`R \subset \text{Cls induct},$$

but the earlier propositions do not need the full hypothesis.

In what follows, note that if $\gamma \epsilon \text{D}`R$, $\gamma - s`\overrightarrow{R_{po}}`\gamma$ is the class of those terms which occur in γ and have never occurred before in any earlier member of D'R. We prove that, with our hypothesis, members of D'R for which this class of new terms is not null form a class which has no last member, and therefore form a progression.

$[(1)]$ $\supset . \text{Cl}`\rho \epsilon \text{ Cls refl}$ (3)

$\vdash . (1) . (2) . (3) . \supset \vdash . \text{Prop}$

The following properties of cardinals which are neither inductive nor reflexive (supposing there are such) are easily proved. Let us put

$$\text{NC med} = \text{N}_0\text{C} - \text{NC induct} - \text{NC refl} \quad \text{Df},$$

$$\text{Cls med} = - \text{Cls induct} - \text{Cls refl} \quad \text{Df},$$

where "med" stands for "mediate." Then

$$\mu \epsilon \text{ NC med} . \supset . \mu +_c 1 \epsilon \text{ NC med} . \mu -_c 1 \epsilon \text{ NC med} . \mu \neq \mu +_c 1 . \mu \neq \mu -_c 1.$$

Hence mediate cardinals have no maximum or minimum.

$$\mu, \nu \epsilon \text{ NC med} . \supset . \mu +_c \nu \epsilon \text{ NC med},$$

$$\mu \epsilon \text{ NC med} . \nu \epsilon \text{ NC med} \cup \text{NC induct} - \iota`0 . \supset . \mu \times_c \nu \epsilon \text{ NC med},$$

whence $\mu \epsilon \text{ NC med} . \supset . \mu^2, \mu^3, \ldots \epsilon \text{ NC med},$

$$\mu^\nu \epsilon \text{ NC med} . \supset : \mu \epsilon \text{ NC med} . \vee . \nu \epsilon \text{ NC med},$$

$$\mu \epsilon \text{ NC med} . \supset . 2^{2^\mu} \epsilon \text{ NC refl},$$

whence $\exists ! \text{ NC med} . \supset . (\exists \nu) . \nu \epsilon \text{ NC med} . 2^\nu \epsilon \text{ NC refl},$

since we have either $\mu \epsilon \text{ NC med} . 2^\mu \epsilon \text{ NC refl}$ or $2^\mu \epsilon \text{ NC med} . 2^{2^\mu} \epsilon \text{ NC refl}$.

$*125$. THE AXIOM OF INFINITY

Summary of $*125$.

The present number is merely concerned to give a few equivalent forms of the axiom of infinity, and of the kindred assumption of the existence of $\aleph_0$.

In virtue of $*125\cdot24\cdot25$ below, if the axiom of infinity holds in any one type, then it holds in any other type which can be derived from this one, or from any type from which this one can be derived. Hence if we assume, as it seems natural to do, that all extensional types are derived from a first type, namely that of individuals, then the axiom of infinity in any such type is equivalent to the assumption that the number of individuals is not inductive.

We deal, in this number, first with equivalent forms of Infin ax, then with equivalent forms of Infin ax (x), then with equivalent forms of $\exists ! \aleph_0$ or $\exists ! \aleph_0(x)$. When "Infin ax" or "$\exists ! \aleph_0$" occurs in this number without typical definition, it and all other typically ambiguous symbols are to be taken in the lowest logically possible types, or with the same *relative* types as if this had been done. The propositions of this number are often not referred to in the sequel, but are here collected together on account of their intrinsic interest.

$*126$. ON TYPICALLY INDEFINITE INDUCTIVE CARDINALS

Recapitulation of Conventions and Summary of $*126$.

We have now arrived at the stage where we can adopt the standpoint of ordinary arithmetic, and can for the future in arithmetical operations with cardinals ignore differences of type. In order to understand how this is so, it will be necessary briefly to recall the line of thought of some of the previous numbers and the conventions upon which the symbolism is based.

The symbolism of $*102$, though perfectly precise as to the typical relations of the various symbols, is in fact too complex for use, except in cases of absolute necessity. It is better to use the typically ambiguous symbols Nc and sm, combined with some simple rules of interpretation of the symbolism, so as to secure that the various occurrences of the same symbols are in their proper relationships of type. This is the course followed in $*100$, $*101$, and in every number from $*110$ onwards.

The important symbols which involve an explicit or implicit use of Nc or sm are called "formal numbers," and it is only necessary to make the rules of interpretation apply to them.

A constant formal number is any symbol representing a typically ambiguous constant such that there is a constant α such that, however the ambiguities of type may be determined, the former constant is identical with $\mathrm{Nc}`\alpha$. The variable formal numbers are defined by enumeration. They are divided into three Sets, the Primary Set, the Argumental Set, and the Arithmetical Set.

The Primary Set consists of $\mathrm{Nc}`\alpha$, $\Sigma\,\mathrm{Nc}`\kappa$, $\Pi\,\mathrm{Nc}`\kappa$, where α is a variable Cls of any type and κ is a variable Cls^2 of any type. Also α and κ may themselves be complex symbols which in some way involve variables.

The Argumental Set has only one member $\mathrm{sm}``\mu$, where $\mu$ is a variable $\mathrm{Cls}^2$ of any type. In its capacity of a formal number $\mathrm{sm}``\mu$ is only interesting when μ is an NC; then $\mathrm{sm}``\mu$ gives the corresponding NC in another type, provided that $\mu$ is not $\Lambda$. Also $\mu$ may be a complex symbol which in some way involves a variable, *e.g.* $\mathrm{sm}``\mathrm{Nc}`\alpha$ is a formal number of the Argumental Set: μ is called the *argument* of $\mathrm{sm}``\mu$.

The Arithmetical Set consists of $\mu +_0 \nu$, $\mu \times_0 \nu$, μ^ν, $\mu -_0 \nu$. These formal numbers are only interesting when μ and ν are also members of NC. Also μ and ν may be complex symbols, so long as one of them at least involves a variable. For example $2^{3+_0\nu}$ is a formal number, and so is $\alpha +_0 (3 +_0 \nu)$.

The Primary and Argumental and Arithmetical Sets of Formal Numbers are derived from the corresponding sets of *variable* formal numbers, by

adding to them the constant formal numbers obtained by substituting constants for the variables occurring in the expressions for the members of the variable set in question.

In the formal numbers of the arithmetical set as written above, μ and ν are called the *first components*. Thus every formal number of this set has two first components. The first components (if any) of the first components are also called *components* of the original formal number, and so on; so that components of components are components of the original symbol.

A formal number of the arithmetical set, whose components are all formal numbers, either constant or variable but *not* belonging to the argumental set, is called a *pure arithmetical* formal number. These are the formal numbers which it is important in arithmetic to secure from assuming the value Λ owing to lowness of type.

The logical investigation of $*100$ and $*101$, where typically ambiguous formal numbers are used, is directly concerned in investigating the premisses necessary to secure various propositions from fluctuating truth-values owing to the intrusion of null-values among the cardinals. The convention, necessary to avoid determinations of type which we never wish to consider, is as follows, where the terms used are explained fully in the prefatory statement:

IT. Argumental occurrences are bound to logical and attributive occurrences; and, if there are no argumental occurrences, equational occurrences are bound to logical occurrences. This rule only applies so far as meaning permits after the assignment of types to the real variables.

In $*110$, $*113$, $*116$, $*119$ we consider the arithmetical operations of addition, multiplication, exponentiation, and subtraction. Also in $*117$ we consider the comparison of cardinal numbers in respect to the relation of greater and less.

There is no interest in complicating our theorems by allowing for the cases when a pure arithmetical formal number, whose components are ambiguous as to type, becomes equal to Λ owing to the low type of one of its *components*. Also in the theory of greater and less the possibility of null-values in low types has no real interest. Accordingly these are excluded from any consideration by the definitions

$$*110{\cdot}03{\cdot}04,\ *113{\cdot}04{\cdot}05,\ *116{\cdot}03{\cdot}04,\ *117{\cdot}02{\cdot}03,$$

as far as members of the primary set of formal numbers are concerned; and for other formal numbers by the following convention:

IIT. Whenever a formal number σ occurs, so that, if it were replaced by $\text{Nc}`\alpha$, the dominant type of $\text{Nc}`\alpha$ would by definition have to be adequate, then the dominant type of σ is also to be adequate.

When σ is a pure arithmetical formal number, this convention secures that the type of every component is adequate.

But in arithmetic we also wish to avoid the intrusion of null-values into the consideration of equations, so far as this avoidance can be attained by the use of high types. Accordingly when we are concerned with the purely arithmetical point of view, we add also the following definition and convention (AT).

Definition. An *arithmetical equation* is an equation between pure arithmetical formal numbers whose dominant types are both determined adequately.

AT. All equations involving pure arithmetical formal numbers are to be arithmetical.

This convention is used in $*117$ and in some earlier propositions which are noted in the prefatory statement.

Its effect is to render the statement of hypotheses often unnecessary. Examples of its application to the numbers where it is not used in the symbolism are also considered in the prefatory statement.

In the case of the inductive numbers we cannot logically prove, apart from Infin ax, that one type exists which is adequate for all the formal numbers 0, 1, 2, 3, etc. But we can prove that for any particular inductive number, say 521, a type exists for which 521 is not equal to Λ. Accordingly for a given symbolic form, in which the symbolism necessarily has only finite complexity, when the types of variables which by hypothesis represent inductive classes or inductive numbers, not Λ, have been settled, it is always possible to fix on a type which will be adequate for all the pure arithmetical formal numbers produced by the symbolism of the form, and also at the same time (and here the peculiar properties of inductive numbers come in) to have chosen the original types of the variables so that any of the variables can assume the value of any assigned constant inductive number, say 521, without being null.

The result is that we may assume that the symbols representing inductive numbers are never null, and thereby obtain the stable truth-values of propositions about them.

Accordingly we proceed as follows: we put

$*$126·01. $\text{NC ind} = \text{NC induct} - \iota{}^{\backprime}\Lambda$ Df

We make the rule that when NC ind appears, convention AT is always applied. The result is that when a formal number is an NC ind we need never think about its type, and accordingly all the conventions vanish from the mind, as far as pure arithmetical indefinite inductive cardinals are concerned. We supersede all other conventions by the single one that, if it has been proved or assumed that a formal number represents an inductive cardinal,

the types are so arranged that that formal number is not equal to Λ. The proofs of propositions in this number consist largely of the production of a definite type in which this result is attained.

The important propositions are

***126·12.** $\vdash : \nu \in \mathrm{NC\,ind} \,.\, \supset \,.\, (\nu +_c 1) \cap t`\nu \in \mathrm{NC\,ind}$

***126·121.** $\vdash \,.\, 1, 2, 3, \ldots \in \mathrm{NC\,ind}$

***126·13·14·15.** $\vdash : \alpha, \beta \in \mathrm{NC\,ind} \,.\, \supset \,.\, \alpha +_c \beta,\ \alpha \times_c \beta,\ \alpha^\beta \in \mathrm{NC\,ind}$

***126·141.** $\vdash : \alpha, \beta \in \mathrm{NC\,ind} - \iota`0 \,.\, \equiv \,.\, \alpha \times_c \beta \in \mathrm{NC\,ind} - \iota`0$

***126·151.** $\vdash : \alpha, \beta \in \mathrm{NC\,ind} - \iota`0 \,.\, \alpha \neq 1 \,.\, \equiv \,.\, \alpha^\beta \in \mathrm{NC\,ind} - \iota`0 - \iota`1$

Also *126·4·42·43 give the fundamental propositions for subtraction, division, and "inverse exponentiation"; and *126·5·51·52·53 the fundamental propositions for the relations of greater and less.

***126·01.** $\mathrm{NC\,ind} = \mathrm{Nc\,induct} - \iota`\Lambda$ Df

Whenever the symbol NC ind is used the *Rule of Indefinite Numbers* is adhered to, so that all consideration of distinctions in type among inductive cardinals can be laid aside (cf. Prefatory Statement and also the Summary of this number).

$*126{\cdot}121$. $\vdash . 1, 2, 3, \ldots \epsilon \mathrm{NC\,ind}$ [$*126{\cdot}11{\cdot}12$]

This proposition, taken in connection with $*120{\cdot}4232$, embodies the convention named the Rule of Indefinite Numbers and its justification. The convention is that 1, 2, 3, ... are always in future to be used in existential types. In other words whenever any particular inductive number is employed, it is determined in a type in which it is not Λ. The justification is that by $*126{\cdot}11{\cdot}12$ such a type can always be found for each particular inductive number.

The convention is also applied to arithmetical formal numbers in $*126{\cdot}13{\cdot}14{\cdot}15$.

For all arithmetical and equational occurrences this convention is really the outcome of IT, IIT, and AT.

PART IV

RELATION-ARITHMETIC

SUMMARY OF PART IV

THE subject to be treated in this Part is a general kind of arithmetic of which ordinal arithmetic is a particular application. The form of arithmetic to be treated in this Part is applicable to all relations, though its chief importance is in regard to such relations as generate series. The analogy with cardinal arithmetic is very close, and the reader will find that what follows is much facilitated by bearing the analogy in mind.

The outlines of relation-arithmetic are as follows. We first define a relation between relations, which we shall call *ordinal similarity* or *likeness*, and which plays the same part for relations as similarity plays for classes. Likeness between P and Q is constituted by the fact that the fields of P and Q can be so correlated by a one-one relation that if any two terms have the relation P, their correlates have the relation Q, and vice versa. If P and Q generate series, we may express this by saying that P and Q are like if their fields can be correlated without change of order. Having defined likeness, our next step is to define the *relation-number* of a relation P as the class of relations which are like P, just as the cardinal number of a class α is the class of classes which are similar to α. We then proceed to addition. The ordinal sum of two relations P and Q is defined as the relation which holds between x and y when x and y have the relation P or the relation Q, or when x is a member of $C\text{‘}P$ and y is a member of $C\text{‘}Q$. If P and Q generate series, it will be seen that this defines the sum of P and Q as the series resulting from adding the Q-series after the end of the P-series. The sum is thus not commutative. The sum of the relation-numbers of P and Q is of course the relation-number of their sum, provided $C\text{‘}P$ and $C\text{‘}Q$ have no common terms.

The ordinal product of two relations P and Q is the relation between two couples $z \downarrow x$, $w \downarrow y$, when x, y belong to $C\text{‘}P$ and z, w belong to $C\text{‘}Q$ and either xPy or $x = y \,.\, zQw$. Thus, for example, if the field of P consists of 1_P, 2_P, 3_P, and the field of Q consists of 1_Q, 2_Q, the relation $P \times Q$ will hold from any earlier to any later term of the following series:

$$1_Q \downarrow 1_P,\ 2_Q \downarrow 1_P,\ 1_Q \downarrow 2_P,\ 2_Q \downarrow 2_P,\ 1_Q \downarrow 3_P,\ 2_Q \downarrow 3_P.$$

It is plain that, denoting the ordinal product of P and Q by $P \times Q$, we have

$$C\text{‘}(P \times Q) = C\text{‘}P \times C\text{‘}Q,$$

where the second "$\times$" as standing between classes has the meaning defined in $*113{\cdot}01$.

Infinite ordinal sums and products will also be defined, but the definitions are somewhat complicated.

The arithmetic which results from the above definitions satisfies all those of the formal laws which are satisfied in ordinal arithmetic, when this is not confined to finite ordinals; that is to say, relation-numbers satisfy the associative law for addition and for multiplication*, they satisfy the distributive law in the shape (where the + and × are those appropriate to relation-numbers)

$$(\beta + \gamma) \times \alpha = (\beta \times \alpha) + (\gamma \times \alpha),$$

and they satisfy the exponential laws

$$\alpha^\beta \times \alpha^\gamma = \alpha^{\beta+\gamma},$$
$$(\alpha^\beta)^\gamma = \alpha^{\beta \times \gamma}.$$

They do not in general satisfy the commutative law either in addition or in multiplication, nor do they satisfy the distributive law in the form

$$\alpha \times (\beta + \gamma) = (\alpha \times \beta) + (\alpha \times \gamma),$$

nor the exponential law

$$\alpha^\gamma \times \beta^\gamma = (\alpha \times \beta)^\gamma.$$

But in the particular case in which the relations concerned are finite serial relations, the corresponding relation-numbers do satisfy these additional formal laws; hence the arithmetic of *finite* ordinals is exactly analogous to that of inductive cardinals (cf. Part V, Section E).

If the relations concerned are limited to well-ordered relations, relation-arithmetic becomes ordinal arithmetic as developed by Cantor; but many of Cantor's propositions, as we shall see in this Part, do not require the limitation to well-ordered relations.

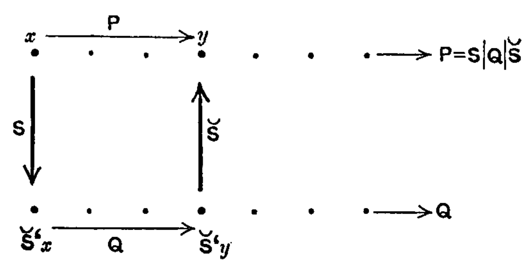
* For the associative law of multiplication, a hypothesis is required as to the kind of relation concerned. Cf. ∗174·241·25.

SECTION A

ORDINAL SIMILARITY AND RELATION-NUMBERS

Summary of Section A.

Two series generated by the relations P and Q respectively are said to be ordinally similar when their terms can be correlated as they stand, without



change of order. In the accompanying figure, the relation S correlates the members of $C\text{‘}P$ and $C\text{‘}Q$ in such a way that if xPy, then $(\breve{S}\text{‘}x)\,Q\,(\breve{S}\text{‘}y)$, and if zQw, then $(S\text{‘}z)\,P\,(S\text{‘}w)$. It is evident that the journey from x to y (where xPy) may, in such a case, be taken by going first to $\breve{S}\text{‘}x$, thence to $\breve{S}\text{‘}y$, and thence back to y, so that $xPy \,.\equiv.\, x\,(S\,|\,Q\,|\,\breve{S})\,y$, *i.e.* $P = S\,|\,Q\,|\,\breve{S}$. Hence to say that P and Q are ordinally similar is equivalent to saying that there is a one-one relation S which has $C\text{‘}Q$ for its converse domain and gives $P = S\,|\,Q\,|\,\breve{S}$. In this case we call S a *correlator* of Q and P.

We denote the relation of ordinal similarity by "smor," which is short for "similar ordinally." Thus

$$P \operatorname{smor} Q \,.\equiv.\, (\exists S) \,.\, S \in 1 \to 1 \,.\, C\text{‘}Q = \text{Ɑ}\text{‘}S \,.\, P = S\,|\,Q\,|\,\breve{S}.$$

It will be found that the relation $S\,|\,Q\,|\,\breve{S}$ plays the same part in relation to Q in relation-arithmetic as $S\text{‘‘}\beta$ plays in relation to β in cardinal arithmetic. It is therefore desirable to have a simpler notation for $S\,|\,Q\,|\,\breve{S}$. We put

$$S;Q = S\,|\,Q\,|\,\breve{S} \quad \text{Df.}$$

We shall find that the semi-colon so defined has the same kind of properties in relation-arithmetic as the two inverted commas have in cardinal arithmetic. Corresponding to the notation $S_\epsilon\text{‘}\beta$, we put

$$S\dagger Q = S\,|\,Q\,|\,\breve{S} \quad \text{Df.}$$

We shall thus have $S\dagger = S \| \breve{S}$. It will appear that $S\dagger$ has ordinal properties analogous to the cardinal properties of S_ϵ. Thus *e.g.* where $S \| \breve{S}_\epsilon$ appears as a cardinal correlator, $S \| \text{Cnv}'S\dagger$ will appear as an ordinal correlator (in each case with the converse domain suitably limited).

The elementary properties of $S;Q$ will be considered in $*150$. We shall then, in $*151$, be able to study ordinal similarity, taking as our definition of an ordinal correlator

$$P \,\overline{\text{smor}}\, Q = \hat{S}\{S \epsilon 1 \to 1 \,.\, C'Q = \text{Ꮧ}'S \,.\, P = S;Q\} \quad \text{Df},$$

and defining two relations as ordinally similar when they have at least one ordinal correlator, *i.e.* putting (on the analogy of $*73$)

$$\text{smor} = \hat{P}\hat{Q}\{\exists ! P \,\overline{\text{smor}}\, Q\} \quad \text{Df}.$$

There is no need to confine the notion of ordinal similarity (or likeness, as we shall also call it) to *serial* relations. When two relations have ordinal similarity, their internal structures are analogous, and they therefore have many common properties. Whenever similarity has been proved between two classes α and β, then if β is given as the field of some relation Q, and S is the correlating relation, $S;Q$ is like Q, and has α for its field. Hence similar classes are the fields of like relations. It must not be supposed, however, that like relations are coextensive with relations whose fields are similar. This does not hold even when we confine ourselves to serial relations, except in the special case of *finite* serial relations.

The definition of relation-numbers ($*152$) is as follows: The relation-number of P, which we call $\text{Nr}'P$, is the class of relations which are ordinally similar to P; and the class of relation-numbers, which we denote by NR, is the class of all classes of the form $\text{Nr}'P$. The elementary properties of relation-numbers, treated in $*152$, are closely analogous to those of cardinal numbers treated in $*100$.

After a few propositions about the ordinal 0 and the ordinal 2, which we call 0_r and 2_r ($*153$), we pass to the consideration of relation-numbers of various types. It will be observed that "smor," like "sm," is a relation which is ambiguous as to the type both of its domain and of its converse domain. Thus "$P \,\text{smor}\, Q$" only has an unambiguous meaning when the types of P and Q are determined. P and Q may or may not be of the same type; the only restriction upon the type of either is that both must be "homogeneous" relations, *i.e.* relations whose domain and converse domain are of the same type. This restriction results from the fact that $C'Q$ occurs in the definition of "$P \,\text{smor}\, Q$," and a relation does not have a field unless it is homogeneous; hence Q must be homogeneous, and therefore, whatever S may be, $S | Q | \breve{S}$ must be homogeneous, *i.e.* P must be homogeneous. Thus *e.g.* such relations as D, ι, or ϵ are not ordinally similar either to themselves

or to anything else. Whenever "$P \operatorname{smor} Q$" is *significant* for a suitable Q, we have $P \operatorname{smor} P$; but if P is not homogeneous, "$P \operatorname{smor} Q$" is never significant. Hence throughout the theory of ordinal similarity, the relations of which ordinal similarity is affirmed or denied must be homogeneous. The correlators, on the contrary, need not be homogeneous.

Owing to the homogeneity of our relations, the types of relation-numbers are much more easily dealt with than they otherwise would be; for the type of a homogeneous relation is determined by that of a single class, namely its field, whereas the type of a relation in general depends upon the types of *two* classes, namely its domain and its converse domain. Since, where likeness is concerned, the type of the field determines the type of the relation, propositions concerning the relations between different typical determinations of a given relation-number are, for the most part, exactly analogous to and deducible from those for cardinals. In fact, a relation ordinally similar to Q exists in the type of P when, and only when, a class similar to $C`Q$ exists in the type of $C`P$, *i.e.*

$$\exists ! \operatorname{Nr}(P)`Q \,.\equiv .\, \exists ! \operatorname{Nc}(C`P)`C`Q.$$

The half of this proposition follows from the fact that, if P is like Q, $C`P$ is similar to $C`Q$. The other half follows from the fact, mentioned above, that if $\beta = C`Q$ and $\alpha \operatorname{sm} \beta$, then there is a relation like $Q$ and having $\alpha$ for its field. Now if $\alpha$ belongs to the type of $C`P$, any relation having α for its field is contained in $t_0`C`P \uparrow t_0`C`P$. Hence in the case supposed there is a relation like Q and contained in $t_0`C`P \uparrow t_0`C`P$. But the relations contained in $t_0`C`P \uparrow t_0`C`P$ constitute $t`P$. Hence there is a relation which is like $Q$ and is a member of $t`P$, whence our proposition results. By means of this proposition and those of $*102$—6, the properties of relation-numbers with respect to types follow easily. The conventions IT, IIT and AT apply to relation-numbers as to cardinals; they are to be applied in the same way as in the analogous propositions of Part III, Section A.

*150. INTERNAL TRANSFORMATION OF A RELATION

Summary of *150.

In this number we introduce two notations which have uses in regard to relations closely analogous to the uses of $R``\alpha$ and R_ϵ in regard to classes. These two notations are defined as follows:

$$S \mathbin{;} Q = S \,|\, Q \,|\, \breve{S} \quad \text{Df},$$

$$S \dagger Q = S \,|\, Q \,|\, \breve{S} \quad \text{Df}.$$

We then have $\quad \vdash . \, S \dagger Q = S \mathbin{;} Q = S \,|\, Q \,|\, \breve{S} = (S \,\|\, \breve{S})`Q.$

$S \dagger Q$ is merely an alternative to $S \mathbin{;} Q$, just as $R_\epsilon`\alpha$ is an alternative to $R``\alpha$. Also $S\dagger = S \,\|\, \breve{S}$, in virtue of *38·01 and *43·01.

The uses of $S \mathbin{;} Q$ occur chiefly when S is a one-one relation and $C`Q \subset \text{Ɑ}`S$. This case is illustrated in the figure in the introduction to this section. Here if Q relates x and y, $S \mathbin{;} Q$ relates $S`x$ and $S`y$. Thus given a class α similar to $C`Q$, if S is the correlating relation, $S \mathbin{;} Q$ has α for its field, and has, in very many respects, properties analogous to those of Q.

$S \mathbin{;} Q$ is important for many special values of S. For example, let Q be a relation between relations; then $C \mathbin{;} Q$ will be the corresponding relation of the fields of these relations. If Q be any relation, $\downarrow x \mathbin{;} Q$ will be the corresponding relation between ordered couples of which x is the relatum; *i.e.* if yQz, the relation $\downarrow x \mathbin{;} Q$ will hold between $y \downarrow x$ and $z \downarrow x$. If Q is a relation between classes, and we have $\beta Q \gamma$, then the relation $\alpha \cup \mathbin{;} Q$ will hold between $\alpha \cup \beta$ and $\alpha \cup \gamma$. In short, whenever S is a one-many relation, and therefore gives rise to a descriptive function, then $S \mathbin{;} Q$ is the relation which holds between $S`y$ and $S`z$ whenever Q holds between y and z.

We introduce one other new notation in this number, corresponding to $\alpha \underset{,,}{♀} y$ in *38. This notation is thus defined:

$$Q \underset{\cdot ;}{♀} y = ♀ y \mathbin{;} Q \quad \text{Df}.$$

The purpose of this notation is to enable us to proceed to $Q \underset{\cdot ;}{♀} \mathbin{;} P$ and other similar notations; or, otherwise stated, to enable us to treat $♀ y \mathbin{;} Q$ as a function of y rather than of Q. Take for example the case of $x \downarrow \mathbin{;} Q$. We may wish to consider various relations $x \downarrow \mathbin{;} Q$, $y \downarrow \mathbin{;} Q$, where we are to have (say) xPy. To express the relation of $x \downarrow \mathbin{;} Q$ to $y \downarrow \mathbin{;} Q$ resulting from xPy, we need the above notation. By its help, we have

$$x \downarrow \mathbin{;} Q = Q \underset{\cdot ;}{\downarrow} `x \, . \, y \downarrow \mathbin{;} Q = Q \underset{\cdot ;}{\downarrow} `y.$$

Hence $\quad xPy \, . \equiv . \, (Q \underset{\cdot ;}{\downarrow} `x) (Q \underset{\cdot ;}{\downarrow} \mathbin{;} P) (Q \underset{\cdot ;}{\downarrow} `y).$

Thus $Q \underset{;}{\downarrow} {;}P$ is the relation between $x \downarrow {;}Q$ and $y \downarrow {;}Q$ corresponding to the relation P between x and y. $Q \underset{;}{\downarrow} {;}P$ plays the same part in relation-arithmetic as is played by $\alpha \underset{,,}{\downarrow} {``}\beta$ in cardinal arithmetic.

The notations of this number are capable of occasional uses in cardinal arithmetic*, but their chief utility is in relation-arithmetic, in which they are fundamental.

In order to minimize the use of brackets, we put

$$R`S{;}Q = R`(S{;}Q) \quad \text{Df},$$
$$R{;}S{;}Q = R{;}(S{;}Q) \quad \text{Df}.$$

As an immediate result of the definition of $S{;}Q$, we have

***150·11.** $\vdash : x\,(S{;}Q)\,y \,.\equiv .\, (\exists z, w) \,.\, xSz \,.\, ySw \,.\, zQw$

We have also

***150·12.** $\vdash . \text{Cnv}`S{;}Q = S{;}\breve{Q}$

***150·13.** $\vdash . R{;}S{;}Q = (R \mid S){;}Q$

This proposition, which is the analogue of $(P \mid Q)``\gamma = P``Q``\gamma$ (*37·33), is very often used. We have also

***150·3.** $\vdash . S{;}(Q \cup R) = S{;}Q \cup S{;}R$

***150·42.** $\vdash . S{;}\dot{\Lambda} = \dot{\Lambda}$

The remaining propositions of this number (with a few exceptions) may be thus classified:

(1) Propositions concerning the domain, converse domain, and field of $S{;}Q$ (*150·2—·23). Owing to the fact that the chief applications of this subject are to cases where Q and $S{;}Q$ are serial, the *field* of $S{;}Q$ is more important than its domain or converse domain. Thus the chief propositions here are

***150·22.** $\vdash : C`Q \subset \text{G}`S \,.\supset .\, C`S{;}Q = S``C`Q$

***150·23.** $\vdash : C`Q = \text{G}`S \,.\supset .\, C`S{;}Q = \text{D}`S$

The hypothesis $C`Q \subset \text{G}`S$ is verified in almost all applications of $S{;}Q$. When it is not verified, the part of $C`Q$ not contained in $\text{G}`S$ is irrelevant to the value of $S{;}Q$. The hypothesis $C`Q = \text{G}`S$ is very often verified in practice, since it is verified when S is a correlator of $S{;}Q$ and Q.

(2) Propositions concerning relations with limited domains, converse domains, or fields (*150·32—·38). Broadly speaking, a limitation on the *field* of Q is equivalent to a limitation on the *converse domain* of S, and both are equivalent to a corresponding limitation on the field of $S{;}Q$ provided

* *E.g.* in *116·53 and following propositions, where the notation $S\dagger$ was introduced by a temporary definition.

$S \in \mathrm{Cls} \rightarrow 1$. The limitations that occur in practice are limitations on the converse domain of S, with consequent limitations on the fields of Q and $S \mathbin{;} Q$.

The chief propositions on this subject are

***150·32.** $\vdash . (S \upharpoonright C'Q) \mathbin{;} Q = S \mathbin{;} Q$

***150·35.** $\vdash :. y \in C'Q . \supset_y . R'y = S'y : \supset . R \mathbin{;} Q = S \mathbin{;} Q$

(This follows from *150·32 and *35·71.)

***150·36.** $\vdash . (S \upharpoonright \beta) \mathbin{;} Q = S \mathbin{;} (Q \mathbin{\text{⫡}} \beta)$

***150·37.** $\vdash : S \in \mathrm{Cls} \rightarrow 1 . \supset . S \mathbin{;} (Q \mathbin{\text{⫡}} \beta) = (S \mathbin{;} Q) \mathbin{\text{⫡}} S``\beta = (S \upharpoonright \beta) \mathbin{;} Q = \{(S``\beta) \upharpoonleft S\} \mathbin{;} Q$

(3) Propositions on $S \mathbin{;} Q$ when S is one-many or many-one (*150·4—·56). We have

***150·4.** $\vdash :. S \in 1 \rightarrow \mathrm{Cls} . \supset : x (S \mathbin{;} Q) y . \equiv . (\exists z, w) . x = S'z . y = S'w . zQw$

This proposition is used constantly. Only slightly less useful is

***150·41.** $\vdash :. S \in \mathrm{Cls} \rightarrow 1 . \supset : x (S \mathbin{;} Q) y . \equiv . (\breve{S}'x) \, Q \, (\breve{S}'y)$

The remaining propositions of this set are chiefly applications of *150·4·41 to special cases.

(4) A few propositions on $Q \underset{\cdot\cdot}{♀} y$ (*150·6—·62). These are immediate consequences of the definition.

(5) A set of propositions on couples and matters connected with them (*150·7—·75). The chief of these is

***150·71.** $\vdash : S \in 1 \rightarrow \mathrm{Cls} . z, w \in \text{Ꭰ}'S . \supset . S \mathbin{;} (z \downarrow w) = (S'z) \downarrow (S'w)$

This proposition is very often used in relation-arithmetic. Useful also is

***150·73.** $\vdash . S \mathbin{;} (\alpha \uparrow \beta) = S``\alpha \uparrow S``\beta$

(6) We next have four propositions (*150·8—·83) on $S \mathbin{;} P$ when P is a power of Q. These belong with the propositions of *92; they are useful in the ordinal theory of finite and infinite. We have

***150·82·83.** $\vdash :. S \in \mathrm{Cls} \rightarrow 1 : \mathrm{D}'Q \subset \text{Ꭰ}'S . \mathrm{v} . \text{Ꭰ}'Q \subset \text{Ꭰ}'S : \supset .$
$\mathrm{Pot}'S \mathbin{;} Q = S\dagger``\mathrm{Pot}'Q . (S \mathbin{;} Q)_{\mathrm{po}} = S \mathbin{;} Q_{\mathrm{po}}$

It follows that, in the hypothesis supposed, if S is a correlator of P and Q, it is also a correlator of P_{po} and Q_{po}.

(7) Propositions concerning the relation $S\dagger$ (*150·14—·171 and *150·9—·94). These have uses analogous to those of propositions concerning S_ϵ. The most important are

***150·14.** $\vdash . R\dagger \mid S\dagger = (R \mid S)\dagger$

(This follows immediately from *150·13, above.)

***150·141.** $\vdash . S\dagger = S \,\|\, \breve{S}$

(This follows immediately from the definition.)

***150·16.** $\vdash . \dot{s}`R\dagger``\lambda = R\dagger(\dot{s}`\lambda) = R\mathbin{;}\dot{s}`\lambda$

This proposition is analogous to $s`R```\kappa = R``s`\kappa$ (*40·38), *i.e.* to

$$s`R_\epsilon``\kappa = R_\epsilon`s`\kappa = R``s`\kappa,$$

as appears on substituting $\dot{s}$ and $R\dagger$ for s and R_ϵ in this variant of *40·38.

The remaining propositions are mainly of the nature of lemmas, to be used once or twice each in relation-arithmetic.

***150·01.** $S\mathbin{;}Q = S \mid Q \mid \breve{S}$ Df

***150·02.** $S\dagger Q = S \mid Q \mid \breve{S}$ Df

***150·03.** $Q \underset{\bullet\,;}{♀} y = ♀ y \mathbin{;} Q$ Df

Here, as in *38, "♀" stands for any sign which, when placed between two letters, defines a descriptive function of the arguments represented by those letters. Thus for example "♀" may represent any of the following:

$$\cap,\ \cup,\ \dot{\cap},\ \dot{\cup},\ \mid,\ \upharpoonleft,\ \upharpoonright,\ \Lsh,\ \uparrow,\ \downarrow.$$

The two following definitions serve merely for the avoidance of brackets.

***150·04.** $R`S\mathbin{;}Q = R`(S\mathbin{;}Q)$ Df

***150·05.** $R\mathbin{;}S\mathbin{;}Q = R\mathbin{;}(S\mathbin{;}Q)$ Df

***150·1.** $\vdash . S\mathbin{;}Q = S \mid Q \mid \breve{S} = (S \parallel \breve{S})`Q = S\dagger Q = S\dagger`Q$
[*43·112 . *38·11 . (*150·01·02)]

***150·11.** $\vdash : x(S\mathbin{;}Q)y . \equiv . (\exists z, w) . xSz . ySw . zQw$ [*34·1 . *31·11]

***150·12.** $\vdash . \text{Cnv}`S\mathbin{;}Q = S\mathbin{;}\breve{Q}$ [*34·2 . *31·33]

***150·13.** $\vdash . R\mathbin{;}S\mathbin{;}Q = (R \mid S)\mathbin{;}Q$

Dem.

$\vdash . *150·1 . (*150·05) . \supset \vdash . R\mathbin{;}S\mathbin{;}Q = R\mathbin{;}(S \mid Q \mid \breve{S})$
[*150·1] $= R \mid S \mid Q \mid \breve{S} \mid \breve{R}$
[*34·2] $= R \mid S \mid Q \mid \text{Cnv}`(R \mid S)$
[*150·1] $= (R \mid S)\mathbin{;}Q . \supset \vdash . \text{Prop}$

***150·131.** $\vdash . (R\mathbin{;}S)\mathbin{;}Q = R\mathbin{;}(S \mid \breve{R})\mathbin{;}Q$

Dem.

$\vdash . *150·13 . \supset \vdash . R\mathbin{;}(S \mid \breve{R})\mathbin{;}Q = (R \mid S \mid \breve{R})\mathbin{;}Q$
[*150·1] $= (R\mathbin{;}S)\mathbin{;}Q . \supset \vdash . \text{Prop}$

Observe that we do not have $(R\mathbin{;}S)\mathbin{;}Q = R\mathbin{;}(S\mathbin{;}Q)$.

***150·14.** $\vdash . R\dagger \mid S\dagger = (R \mid S)\dagger$

Dem.

$\vdash . *150·1·13 . \supset \vdash . R\dagger`S\dagger`Q = (R \mid S)\dagger`Q$ (1)
$\vdash . (1) . *34·42 . \supset \vdash . \text{Prop}$

This proposition is the relational analogue of *37·34.

$*150{\cdot}141.\ \vdash . S\dagger = S \| \breve{S} \quad [*150{\cdot}1 . *30{\cdot}41]$

$*150{\cdot}15.\ \vdash . S\dagger \in 1 \to \mathrm{Cls} \quad [*72{\cdot}14]$

$*150{\cdot}151.\ \vdash :. (x) . E ! S\text{‘}x : S \in \mathrm{Cls} \to 1 : \supset . S\dagger \in 1 \to 1 \quad [*74{\cdot}772 . *150{\cdot}141]$

The following proposition is used in the theory of double ordinal similarity ($*164{\cdot}13$).

$*150{\cdot}152.\ \vdash : S \upharpoonright s\text{‘}C\text{“}\lambda \in \mathrm{Cls} \to 1 . s\text{‘}C\text{“}\lambda \subset \text{Ɑ}\text{‘}S . \supset . (S\dagger) \upharpoonright \lambda \in 1 \to 1$

Dem.

$\vdash . *74{\cdot}775 \dfrac{S, S}{Q, R} . \supset$

$\vdash : S \upharpoonright s\text{‘}C\text{“}\lambda \in \mathrm{Cls} \to 1 . s\text{‘}\mathrm{D}\text{“}\lambda \subset \text{Ɑ}\text{‘}S . s\text{‘}\text{Ɑ}\text{“}\lambda \subset \text{Ɑ}\text{‘}S . \supset .$

$$(S \| \breve{S}) \upharpoonright \lambda \in 1 \to 1 \qquad (1)$$

$\vdash . (1) . *40{\cdot}57 . *150{\cdot}141 . \supset \vdash . \mathrm{Prop}$

$*150{\cdot}153.\ \vdash :. S \upharpoonright s\text{‘}C\text{“}\lambda \in \mathrm{Cls} \to 1 . s\text{‘}C\text{“}\lambda \subset \text{Ɑ}\text{‘}S . Q, R \in \lambda . \supset :$
$S;Q = S;R . \supset . Q = R$

Dem.

$*150\cdot22$. $\vdash : C\text{‘}Q \subset \text{Ɑ}\text{‘}S . \supset . C\text{‘}S\mathbin{;}Q = S\text{“}C\text{‘}Q$ [$*150\cdot21\cdot211 . *37\cdot22$]

In practice, when $S\mathbin{;}Q$ is used, we almost always have $C\text{‘}Q \subset \text{Ɑ}\text{‘}S$. For the use of $S\mathbin{;}Q$ is to obtain a relation analogous to Q and having a different field; now $S\mathbin{;}Q$ is analogous to $Q \upharpoonright \text{Ɑ}\text{‘}S$, for the part of $C\text{‘}Q$ which lies outside $\text{Ɑ}\text{‘}S$ is unaffected by S. Hence if we have, to start with, a relation Q whose field is *not* contained in $\text{Ɑ}\text{‘}S$, we shall usually find it profitable to limit the field to $\text{Ɑ}\text{‘}S$, and consider the transformed relation rather as $S\mathbin{;}(Q \upharpoonright \text{Ɑ}\text{‘}S)$ than as $S\mathbin{;}Q$. Thus the hypothesis $C\text{‘}Q \subset \text{Ɑ}\text{‘}S$ will be verified in almost all useful applications of the notion of $S\mathbin{;}Q$.

The above proposition is used in dealing with the correlation of series (*208·2).

***150·4.** $\vdash :. S \in 1 \to \mathrm{Cls} . \supset : x (S;Q) y . \equiv . (\exists z, w) . x = S'z . y = S'w . zQw$
[*150·11 . *71·36]

This proposition is fundamental in the theory of $S;Q$, because in most of the uses of this notion S is one-many. The proposition states that when S is one-many, $S;Q$ is the relation between the S's of terms related by Q. Thus if S is the relation of wife to husband, and Q is the relation of brother to brother, $S;Q$ is the relation between wives of brothers. If Q is a relation between relations, $C;P$ will be the corresponding relation of their fields; and so on.

***150·41.** $\vdash :. S \in \mathrm{Cls} \to 1 . \supset : x (S;Q) y . \equiv . (\breve{S}'x) \, Q \, (\breve{S}'y)$ [*150·11 . *71·331]

$s\text{‘}C\text{“}C\text{‘}P \subset \mathrm{D}\text{‘}S . s\text{‘}C\text{“}C\text{‘}Q \subset \text{\reflectbox{D}}\text{‘}S . Q = \breve{S}\dagger;P \quad (3)$

$\vdash . (1) . (2) . (3) . \supset \vdash . \mathrm{Prop}$

The above proposition is the analogue of $*74\cdot61$, which (with a few trivial transformations) may be written

$$\vdash :. S \in 1 \to 1 . \supset : s\text{‘}\lambda \subset \text{\reflectbox{D}}\text{‘}S . \kappa = S_\epsilon\text{“}\lambda . \equiv . s\text{‘}\kappa \subset \mathrm{D}\text{‘}S . \lambda = (\breve{S})_\epsilon\text{“}\kappa .$$

In obtaining ordinal analogues of such propositions, S_ϵ will be replaced by $S\dagger$, and the two inverted commas will be replaced by the semi-colon; a class of classes κ will be replaced, in most of its occurrences, by a relation of relations P, but will sometimes be replaced by $C``C`P$.

The above proposition (*150·94) is used in proving that the converse of a double correlator of P and Q is a double correlator of Q and P (*164·21). The corresponding cardinal proposition (*111·131) uses *74·6, which is practically the same proposition as *74·61, which is the analogue of *150·94.

The above proposition is used in the theory of ordinal exponentiation (*176·21).

$*151$. ORDINAL SIMILARITY

Summary of $*151$.

In this number, we give the definition of ordinal similarity, and various equivalent forms; we prove that ordinal similarity is reflexive ($*151\cdot13$), symmetrical ($*151\cdot14$) and transitive ($*151\cdot15$), and we give some particular cases of ordinal similarity ($*151\cdot6$ ff.). Propositions in this number should be compared with those in $*73$, to which they are analogous.

The class of ordinal correlators of P and Q is written $P \,\overline{\text{smor}}\, Q$, where "smor" stands for "similar ordinally." We put

$$P \,\overline{\text{smor}}\, Q = \hat{S}\{S \in 1 \rightarrow 1 \,.\, C\text{`}Q = \mathrm{G}\text{`}S \,.\, P = S;Q\} \quad \text{Df.}$$

(We might equally well put

$$P \,\overline{\text{smor}}\, Q = (1 \rightarrow 1) \cap \overleftarrow{\mathrm{G}}\text{`}C\text{`}Q \cap \overleftarrow{\dagger Q}\text{`}P \quad \text{Df,}$$

which is an equivalent but more condensed form of the definition.) We then define "P is ordinally similar to Q" as meaning that there is at least one ordinal correlator of P and Q, *i.e.*

$$\text{smor} = \hat{P}\hat{Q}(\exists \,!\, P \,\overline{\text{smor}}\, Q) \quad \text{Df.}$$

We shall find that if P and Q generate well-ordered series, they have at most one correlator ($*250\cdot6$), but this does not hold in general for other series.

After giving the elementary properties of ordinal similarity, we have three important propositions on its connection with cardinal similarity, namely: ($*151\cdot18$) if P is similar to Q, the field of P is similar to the field of Q (the converse does not hold in general, but holds if P and Q are finite serial relations); ($*151\cdot19$) if $C\text{`}P$ is similar to $C\text{`}Q$, there is a relation R similar to Q and having $C\text{`}P$ for its field, and vice versa; ($*151\cdot191$) $S$ is an ordinal correlator of $P$ and $Q$ when, and only when, it is a cardinal correlator of $C\text{`}P$ and $C\text{`}Q$ and $P = S;Q$.

We then have a set of propositions on correlators of the form $S \upharpoonright C\text{`}Q$ ($*151\cdot2$—$\cdot243$). Most of the correlators with which we shall be concerned are of this form. The most useful proposition here is

$*151\cdot22$. $\vdash : S \upharpoonright C\text{`}Q \in 1 \rightarrow 1 \,.\, C\text{`}Q \subset \mathrm{G}\text{`}S \,.\, P = S;Q \,.\equiv.\, S \upharpoonright C\text{`}Q \in P \,\overline{\text{smor}}\, Q$

A useful consequence of this proposition is

$*151\cdot231$. $\vdash :. (y) \,.\, \mathrm{E}\,!\, S\text{`}y : S \upharpoonright C\text{`}Q \in 1 \rightarrow 1 \,.\, P = S;Q : \supset .\, S \upharpoonright C\text{`}Q \in P \,\overline{\text{smor}}\, Q$

This consequence is useful because the hypothesis $(y) \,.\, \mathrm{E}\,!\, S\text{`}y$ is satisfied by most of the relations which occur as correlators.

We have next a number of propositions on the inferribility of $Q = \breve{S};P$ or $Q \subseteq \breve{S};P$ from $P = S;Q$ or $P \subseteq S;Q$, and connected matters (*151·25—·29). We have

***151·25.** $\vdash : S \in \mathrm{Cls} \to 1 \,.\, C`Q \subset \text{ᗡ}`S \,.\, P = S;Q \,.\supset .\, Q = \breve{S};P$

***151·26.** $\vdash :. S \in \mathrm{Cls} \to 1 \,.\, C`Q \subset \text{ᗡ}`S \,.\supset : P \subseteq S;Q \,.\supset .\, \breve{S};P \subseteq Q :$
$S;Q \subseteq P \,.\supset .\, Q \subseteq \breve{S};P$

***151·29.** $\vdash :. P \,\mathrm{smor}\, Q \,.\equiv : (\exists S) : xPy \,.\supset_{x,y} .\, (\breve{S}`x)\, Q\, (\breve{S}`y) :$
$zQw \,.\supset_{z,w} .\, (S`z)\, P\, (S`w)$

*151·29 is never used, but is inserted in order to show that our definition of "ordinal similarity" agrees with what is commonly understood by that term. If P and Q are regarded as serial, so that "xPy" means "x precedes y in the P-series," and "zQw" means "z precedes w in the Q-series," then our proposition states that two series are ordinally similar when their terms can be so correlated that predecessors in either are correlated with predecessors in the other, and successors with successors, *i.e.* when the two series can be correlated without change of order.

We have next (*151·31—·52) a set of miscellaneous propositions, of which the most useful are

***151·401.** $\vdash : T \upharpoonright C`P \in X \,\overline{\mathrm{smor}}\, P \,.\, T \upharpoonright C`Q \in Y \,\overline{\mathrm{smor}}\, Q \,.\, S \in P \,\overline{\mathrm{smor}}\, Q \,.\supset .$
$T;S \in X \,\overline{\mathrm{smor}}\, Y$

***151·5.** $\vdash : S \upharpoonright C`Q \in P \,\overline{\mathrm{smor}}\, Q \,.\supset .\, \mathrm{D}`P = S``\mathrm{D}`Q \,.\, \text{ᗡ}`P = S``\text{ᗡ}`Q \,.\, \overrightarrow{B}`P = S``\overrightarrow{B}`Q \,.$
$\overrightarrow{B}`\breve{P} = S``\overrightarrow{B}`\breve{Q}$

*151·401 will be useful in such cases as the following: Let P and Q be relations between relations, then $\mathrm{D};P$ and $\mathrm{D};Q$ will be the corresponding relations of their domains. Suppose $\mathrm{D} \upharpoonright C`P$, $\mathrm{D} \upharpoonright C`Q \in 1 \to 1$. Then, by *151·401, if S is a correlator of P and Q, $\mathrm{D};S$ is a correlator of $\mathrm{D};P$ and $\mathrm{D};Q$.

*151·5 shows that if S is a correlator of P and Q, it correlates $\mathrm{D}`P$ with $\mathrm{D}`Q$, $\text{ᗡ}`P$ with $\text{ᗡ}`Q$, $\overrightarrow{B}`P$ with $\overrightarrow{B}`Q$, and $\overrightarrow{B}`\breve{P}$ with $\overrightarrow{B}`\breve{Q}$.

Our next set of propositions (*151·53—·59) is concerned with the correlation of powers of P and Q and kindred matters. We show (*151·55) that a correlator of P and Q is also a correlator of P_{po} and Q_{po}, and therefore if P and Q are similar, so are P_{po} and Q_{po} (*151·56); we show also (*151·59) that if P and Q are similar, so are P_ν and Q_ν. These propositions are used in the theory of progressions (*263·17).

The remaining propositions (*151·6 to the end) are concerned with applications to particular cases. The most useful of these are

***151·61.** $\vdash .\, \iota;P \,\mathrm{smor}\, P$

which shows how to raise the type of a relation without changing its relation-number;

***151·64.** $\vdash . x \downarrow {}^{;}P \operatorname{smor} P . (x \downarrow) \upharpoonright C‘P \in (x \downarrow {}^{;}P) \overline{\operatorname{smor}} P$

***151·65.** $\vdash . \downarrow x {}^{;}P \operatorname{smor} P . (\downarrow x) \upharpoonright C‘P \in (\downarrow x {}^{;}P) \overline{\operatorname{smor}} P$

We prove also that all members of 2_r (*i.e.* all relations of the form $x \downarrow y$, where $x \neq y$) are similar (*151·63), and that all relations of the form $x \downarrow x$ are similar (*151·631).

***151·01.** $P \overline{\operatorname{smor}} Q = \hat{S}\{S \in 1 \to 1 . C‘Q = \text{ᗡ}‘S . P = S {}^{;} Q\}$ Df

***151·02.** $\operatorname{smor} = \hat{P}\hat{Q}\{\exists ! P \overline{\operatorname{smor}} Q\}$ Df

$*151\cdot23.\ \ \vdash : P \operatorname{smor} Q . \equiv . (\exists S) . S \upharpoonright C\text{‘}Q \in 1 \to 1 . C\text{‘}Q \subset \text{Ɑ}\text{‘}S . P = S;Q$ [$*151\cdot22$]

The above proposition ($*151\cdot23$) is very useful. It is the analogue of $*73\cdot15$. (It should be observed that, in all propositions concerning likeness, $S;Q$ plays the same part as $S\text{‘‘}\beta$ plays in propositions concerning similarity.) By means of $*151\cdot23$, we can establish likeness in all those numerous cases in which a relation which is not usually one-one becomes one-one when confined to a certain converse domain, as for example if we have to deal with $\mathrm{D} \upharpoonright \epsilon_\Delta\text{‘}\kappa$, where $\kappa \in \mathrm{Cls}^2 \operatorname{excl}$, or with $\mathrm{D} \upharpoonright P_\Delta\text{‘}\kappa$, where $P \upharpoonright \kappa \in \mathrm{Cls} \to 1$. Thus *e.g.* by the above proposition, if Q is any relation whose field is $P_\Delta\text{‘}\kappa$, where $P \upharpoonright \kappa \in \mathrm{Cls} \to 1$, $\mathrm{D};Q$ will be an ordinally similar relation whose field is $\mathrm{D}\text{‘‘}P_\Delta\text{‘}\kappa$.

The above proposition shows that ordinal similarity as we have defined it has the properties which are commonly associated with the term "ordinal similarity," namely that P and Q are ordinally similar when their fields can be so correlated that two terms having the relation P are always correlated with two terms having the relation Q, and vice versa.

The hypothesis $S \in 1 \to 1$ is redundant in *151·28; this is shown in the following proposition.

***151·281.** $\vdash :. xPy . \supset_{x,y} . (\breve{S}`x) \, Q \, (\breve{S}`y) : zQw . \supset_{z,w} . (S`z) \, P \, (S`w) :$

$*152$. DEFINITION AND ELEMENTARY PROPERTIES OF RELATION-NUMBERS

Summary of $*152$.

The relation-number of P, which we denote by $\text{Nr}'P$, is defined as the class of relations which are ordinally similar to P, *i.e.*

$$\text{Nr}'P = \overrightarrow{\text{smor}}'P.$$

Hence our definition is

$$\text{Nr} = \overrightarrow{\text{smor}} \quad \text{Df.}$$

The class of relation-numbers consists of all such classes as $\text{Nr}'P$, *i.e.*

$$\text{NR} = \text{D}'\text{Nr} \quad \text{Df.}$$

These two definitions are analogous to those of $*100$, merely substituting "smor" for "sm." They are justified by similar considerations, and lead to similar results. With the exception of $*152 \cdot 7 \cdot 71 \cdot 72$, the propositions of this number are the analogues of those of $*100$, and call for no remarks other than those in the introduction to $*100$ (*mutatis mutandis*).

$*152 \cdot 7 \cdot 71 \cdot 72$ give relations between relation-numbers and cardinals. $*152 \cdot 7$, which is constantly used, states that the cardinal number of $C'Q$ consists of the fields of the relation-number of Q, *i.e.* the classes similar to $C'Q$ are the fields of the relations similar to Q; in symbols,

$*152 \cdot 7$. $\vdash . \text{Nc}'C'Q = C``\text{Nr}'Q$

Hence it follows that the fields of a relation-number form a cardinal number, *i.e.*

$*152 \cdot 71$. $\vdash : \mu \in \text{NR} . \supset . C``\mu \in \text{NC}$

Hence also it follows that cardinals other than Λ consist of classes of the form $C``\mu$, where μ is a relation-number other than Λ, *i.e.*

$*152 \cdot 72$. $\vdash . \text{NC} - \iota'\Lambda = C```(\text{NR} - \iota'\Lambda)$

In $*154 \cdot 9$, we shall show how to remove the restriction to numbers other than Λ, thus arriving at

$$\vdash . \text{NC} = C```\text{NR}.$$

$*152 \cdot 01$. $\text{Nr} = \overrightarrow{\text{smor}}$ Df

$*152 \cdot 02$. $\text{NR} = \text{D}'\text{Nr}$ Df

$*152 \cdot 1$. $\vdash . \text{Nr}'P = \hat{Q}(Q \,\text{smor}\, P) = \hat{Q}(P \,\text{smor}\, Q)$

$\vdash . (2) . ∗152·11 . \supset \vdash . \text{Prop}$

In the above proposition, the same remarks as to types are to be made as in the case of ∗100·35. If in a certain type $\text{Nr}'P$ and $\text{Nr}'Q$ are both null, we have in that type $\text{Nr}'P = \text{Nr}'Q$, but we need not have $P \text{ smor } Q$. Thus for example we shall find that, in the type of $x \downarrow x$,

$$\text{Nr}'(t^{2}{}'x \uparrow t^{2}{}'x) = \Lambda = \text{Nr}'(t^{3}{}'x \uparrow t^{3}{}'x).$$

But we do not have

$$(t^{2}{}'x \uparrow t^{2}{}'x) \text{ smor } (t^{3}{}'x \uparrow t^{3}{}'x).$$

[Proof as in *100·53]

***152·6.** $\vdash \,.\, \iota ; P \in \mathrm{Nr}`P$ [*151·61]

***152·62.** $\vdash \,.\, x \downarrow ; P \in \mathrm{Nr}`P$ [*151·64]

***152·63.** $\vdash \,.\, \downarrow x ; P \in \mathrm{Nr}`P$ [*151·65]

The utility of *152·6·62·63 is that they enable us to raise the type of a relation-number to any required extent. Thus $\iota ; P$ gives a relation whose field is a class of the next type above that of $C`P$, *i.e.* of the type $t^2`C`P$; while $x \downarrow ; P$ gives a relation whose field is $x \downarrow `` C`P$, which is of the type $t`t`(\iota`x \uparrow C`P)$. If $x \in C`P$, or, more generally, if $x \in t_0`C`P$, this is the type $t^2`P$. Thus if we put $Q = x \downarrow ; P$, we have

$$t`Q = t`(C`Q \uparrow C`Q) = t`(t`P \uparrow t`P) = t`(P \downarrow P).$$

Thus $x \downarrow ; P$ is a relation whose field consists of terms of the same type as P.

The following propositions on the relations of cardinals and relation-numbers are very important.

We shall show in *154·9 that the exclusion of Λ in *152·72 is unnecessary.

*153. THE RELATION-NUMBERS 0_r, 2_r AND 1_s

Summary of *153.

The relation-numbers 0_r and 2_r have already been defined (in *56), though it remains for the present number to show that they are relation-numbers. They are the ordinal 0 and 2 respectively, *i.e.* they are the ordinal numbers of series of no terms and series of two terms respectively. But there is no means of introducing an ordinal 1 which shall be analogous to the cardinal 1 as completely as 0_r and 2_r are analogous to 0 and 2. The only relations whose fields are unit classes are relations of the form $x \downarrow x$. We therefore put

***153·01.** $1_s = \hat{R}\{(\exists x) . R = x \downarrow x\}$ Df

The above definition gives the nearest possible approach to an ordinal 1. 1_s so defined is a relation-number, and is the relation-number corresponding to 1 in the sense that it is the relation-number of all such relations as have a field consisting of one term. But 1_s is not what is called an "ordinal number," because this term is confined by usage to the relation-numbers of well-ordered series, and $x \downarrow x$ is not a serial relation. It is essential to a serial relation to be contained in diversity; and if, by definition, we include $x \downarrow x$ among series, we introduce more exceptions than we avoid. Moreover 1_s does not have the kind of properties which we wish 1 to have; *e.g.* $1_s \dot{+} 1_s$ is not 2_r.

We do not use 1_r, because we shall at a later stage define ν_r as the class of those *well-ordered series* whose fields have ν terms, so that $1_r = \Lambda$, while 0_r and 2_r have the values $\iota`\dot{\Lambda}$ and $\hat{R}\{(\exists x, y) . x \neq y . R = x \downarrow y\}$, as already defined. On account of this general definition of ν_r, we choose a different symbol for the relation-number 1, and 1_s has the merit of being as like 1_r as possible.

To illustrate, by anticipation, the way in which 1_s differs from proper ordinal numbers, we may point out that if 1_s is added to 2_r, we do not obtain 3_r. We shall define 3_r as the class of series which consist of three terms, *i.e.* the class of relations of the form

$$x \downarrow y \cup x \downarrow z \cup y \downarrow z,$$

where $x \neq y . x \neq z . y \neq z$. We shall define the sum of two ordinal numbers as the ordinal number of the sum of two relations having these ordinal numbers (cf. *180), and it will appear that if P and Q are relations whose fields have no members in common, then

$$P \cup Q \cup C`P \uparrow C`Q$$

has a relation-number which is the sum of those of P and Q. Suppose now

$P = x \downarrow y$ and $Q = z \downarrow z$, where $x \neq y \,.\, x \neq z \,.\, y \neq z$. Then

$$P \cup Q \cup C'P \uparrow C'Q = x \downarrow y \cup x \downarrow z \cup y \downarrow z \cup z \downarrow z.$$

This is not a member of 3_r, because of the additional term $z \downarrow z$. Thus the addition of one term to a series P does not give the same number as results from the addition of 1_s to Nr'P. Hence the addition of 1 to an ordinal number has to be separately treated*.

We prove in this number that $0_r = \mathrm{Nr}'\dot{\Lambda}$ (*153·11), that $2_r = \mathrm{Nr}'(\Lambda \downarrow \iota' x)$ (*153·24; observe that we have to take a couple of *classes* (or relations) in order to be sure of the existence of two different objects of the class in question), and that $1_s = \mathrm{Nr}'(y \downarrow y)$ (*153·32). We prove $C''0_r = 0$ (*153·18), $C''2_r = 2$ (*153·212), and $C''1_s = 1$ (*153·36). We have also $\breve{C}''0 = 0_r$ (not proved) and $\breve{C}''1 = 1_s$ (*153·301). But we do not have $\breve{C}''2 = 2_r$; *e.g.* $(x \downarrow y \cup y \downarrow x) \in \breve{C}''2$ if $x \neq y$, but $(x \downarrow y \cup y \downarrow x) \sim\in 2_r$. We have $\exists ! 0_r$ (*153·12) and $\exists ! 1_s$ (*153·34), but from our primitive propositions we cannot deduce $\exists ! 2_r$ unless we rise above the lowest type of relations. The case is exactly analogous to that of $\exists ! 2$ (cf. *101); we have

***153·26·262.** $\vdash . \exists ! 2_r \cap \mathrm{Rl}'(\mathrm{Cls} \uparrow \mathrm{Cls}) . \exists ! 2_r \cap \mathrm{Rel}^2$

But if, as monists aver, there is only one individual, we shall not have $\exists ! 2_r$ in the type of relations of individuals to individuals. Our primitive propositions do not suffice to disprove this supposition.

$*154.$ RELATION-NUMBERS OF ASSIGNED TYPES

Summary of $*154$.

This number gives propositions analogous to those of $*102$. In accordance with our general notations for typical definiteness, "$\mathrm{Nr}(P)\text{‘}Q$" means "the class of relations like Q and of the same type as P," "$\mathrm{Nr}(P_Q)$" means "the relation to a relation of the type of Q of the class of relations like it and of the type of P." By a special definition, "$\mathrm{NR}^Q(P)$" is to mean all typically definite relation-numbers of the form "$\mathrm{Nr}(P_Q)\text{‘}R$," *i.e.* all relation-numbers generated by the relation $\mathrm{Nr}(P_Q)$, *i.e.* the domain of $\mathrm{Nr}(P_Q)$.

Existence-theorems in this subject can be proved by means of $*154 \cdot 14$, which states that relations like Q exist in the type of P when, and only when, classes similar to $C\text{‘}Q$ exist in the type of $C\text{‘}P$. In virtue of this proposition, the existence-theorems of our present topic are deducible from those for cardinals. In symbols, this proposition is

$*154 \cdot 14.$ $\vdash : \exists ! \, \mathrm{Nr}(P)\text{‘}Q \, . \equiv . \, \exists ! \, \mathrm{Nc}(C\text{‘}P)\text{‘}C\text{‘}Q$

Hence by $*102 \cdot 73$ we deduce

$*154 \cdot 242.$ $\vdash . \, \Lambda \in \mathrm{NR}^{\iota\text{‘}P}(P)$

whence, by $*152 \cdot 72$,

$*154 \cdot 9.$ $\vdash . \, \mathrm{NC} = C\text{“}\mathrm{NR}$

The remaining propositions are chiefly analogues of those in $*102$. Very few of them are subsequently referred to.

$*154 \cdot 01.$ $\mathrm{NR}^Y(X) = \mathrm{D}\text{‘}\mathrm{Nr}(X_Y)$ Df

***154·14.** $\vdash : \exists ! \, \mathrm{Nr}(P)`Q \,.\equiv.\, \exists ! \, \mathrm{Nc}(C`P)`C`Q$ [*154·13 . (*65·04)]

In virtue of *154·14 and the propositions of *102, *103, *104, *105, *106, we see that all homogeneous or ascending relation-numbers exist, while Λ is a member of every descending type of relation-numbers. Remembering that the relations concerned must be homogeneous, we see that there are two kinds of steps by which their types may be raised, namely (1) from P to relations of the type of $t`C`P \uparrow t`C`P$, *i.e.* from P to relations of the type of $C`P \downarrow C`P$, or of $\iota ; P$; (2) from P to relations of the type of $t`P \uparrow t`P$, *i.e.* from P to relations of the type of $P \downarrow P$, or of $\downarrow x ; P$ if $x \in t_0`C`P$. Thus repetitions of the two steps from P to $\iota ; P$, and from P to $\downarrow x ; P$, where $x \in t_0`C`P$, will enable us, without changing the relation-number, to raise its type indefinitely. It will be observed that, in accordance with our general definitions for relative types, the type of $\iota ; P$ is $t^{11}`C`P$, and the type of $\downarrow x ; P$ (where $x \in t_0`C`P$) is $t^{11}`P$.

$*155$. HOMOGENEOUS RELATION-NUMBERS

Summary of $*155$.

A relation-number is called *homogeneous* when it is generated by a homogeneous relation of likeness, *i.e.* when it consists of all relations which are like a given relation P and of the same type as P. For the homogeneous relation-number of P we write "$\mathrm{N_0r}`P$"; thus $\mathrm{N_0r}`P = \mathrm{Nr}`P \cap t`P$. When P is given, $\mathrm{N_0r}`P$ is typically definite. We have always $P \epsilon \mathrm{N_0r}`P$, hence $\exists ! \mathrm{N_0r}`P$. Conversely, if a typically definite relation-number is not null, it is a homogeneous relation-number; in fact, if $P$ is a member of it, it is $\mathrm{N_0r}`P$. Thus the homogeneous relation-numbers are all the relation-numbers except Λ.

Homogeneous relation-numbers play the same part in relation-arithmetic as homogeneous cardinals play in cardinal arithmetic. The propositions of this number (except $*155{\cdot}6{\cdot}61$) are the analogues of those with the same decimal part in $*103$. Their proofs are exactly analogous to the proofs of their analogues in $*103$, and are therefore omitted.

The following propositions are the most useful in this number.

$*155{\cdot}11$. $\vdash : Q \epsilon \mathrm{N_0r}`P . \equiv . Q \,\mathrm{smor}\, P . Q \epsilon t`P . \equiv . Q \epsilon \mathrm{Nr}`P . Q \epsilon t`P$

This merely embodies the definition.

$*155{\cdot}12$. $\vdash . P \epsilon \mathrm{N_0r}`P$

whence

$*155{\cdot}13$. $\vdash . \exists ! \mathrm{N_0r}`P$

$*155{\cdot}16$. $\vdash : \mathrm{N_0r}`P = \mathrm{Nr}`Q . \equiv . \mathrm{Nr}`P = \mathrm{Nr}`Q$

This proposition is used in the theory of well-ordered series ($*253$ and $*255$). It requires that the equation "$\mathrm{Nr}`P = \mathrm{Nr}`Q$" on the right-hand side should be subject to the convention AT. Otherwise, the typical ambiguities might be so determined as to give $\mathrm{Nr}`P = \mathrm{Nr}`Q = \Lambda$, which would not imply $\mathrm{N_0r}`P = \mathrm{Nr}`Q$.

$*155{\cdot}2$. $\vdash : \mu \epsilon \mathrm{N_0R} . \equiv . (\exists P) . \mu = \mathrm{Nr}`P \cap t`P . \equiv . (\exists P) . \mu = \mathrm{N_0r}`P$

This merely embodies the definition of $\mathrm{N_0R}$.

$*155{\cdot}22$. $\vdash : \mu \epsilon \mathrm{N_0R} . \supset . \exists ! \mu$

$*155{\cdot}26$. $\vdash :. \mu \epsilon \mathrm{NR} . \supset : P \epsilon \mu . \equiv . \mathrm{N_0r}`P = \mu$

$*155{\cdot}27$. $\vdash : \mu = \mathrm{N_0r}`P . \equiv . \mu \epsilon \mathrm{NR} . P \epsilon \mu$

$*155{\cdot}34$. $\vdash . \mathrm{NR} - \iota`\Lambda \subset \mathrm{N_0R}$

*155·4. $\vdash . \text{smor}``\text{N}_0\text{r}`P = \text{Nr}`P$

*155·5. $\vdash . 0_r \in \text{N}_0\text{R}$

*155·6. $\vdash . C``\text{N}_0\text{r}`P = \text{N}_0\text{c}`C`P$

This last proposition connects homogeneous relation-numbers with homogeneous cardinals.

*155·61. $\vdash . C```\mathrm{N_0R} = \mathrm{N_0C}$ [*155·6]

On ascending and descending relation-numbers, propositions analogous to those of *104, *105, and *106 might be proved by proofs analogous to those given in those numbers. It is, however, scarcely necessary to add anything to the propositions already proved, namely *154·24·241·242·25·251 on descending relation-numbers, *154·26·261·262·31·311·32·321·322·33·331 on ascending relation-numbers, and *155·23·34 giving the relations of non-homogeneous to homogeneous relation-numbers. Ascending relation-numbers all exist, and those that start from the type of P, wherever they end*, are the correspondents† of the homogeneous relation-numbers of the type of P, and are only some of the homogeneous relation-numbers of the type in which they end. Descending relation-numbers consist of Λ together with the homogeneous relation-numbers of the type in which they end: they are the correspondents of only some of the type in which they begin, or rather, Λ is the common correspondent of all those relation-numbers in the initial type which are not correspondents of any homogeneous relation-number in the end-type. These properties are exactly the same as in the case of cardinals, as might be foreseen by *154·14.

* We say that $\mathrm{Nr}\,(P)`Q$ starts from the type of Q and ends in the type of P.

† We call two typically definite relation-numbers *correspondents* when they only differ as to the typical determination, *i.e.* $\mathrm{Nr}\,(X)`P$ and $\mathrm{Nr}\,(Y)`P$ are correspondents.

SECTION B

ADDITION OF RELATIONS, AND THE PRODUCT OF TWO RELATIONS

Summary of Section B.

In the present section, we have to consider the kind of addition of relations which is required in ordinal arithmetic. In cardinal arithmetic, if κ is a class of mutually exclusive classes, $s'\kappa$ has the properties required of their sum, and thus we do not require a new kind of logical addition before dealing with arithmetical addition. But in ordinal arithmetic this is not so. Suppose P and Q are the generating relations of two series, and we wish to add the Q-series at the end of the P-series. Then we wish every term of the P-series to precede every term of the Q-series; thus $P \mathbin{\dot\cup} Q$ is not the generating relation of the new series, since $P \mathbin{\dot\cup} Q$ gives no relation between the terms of the P-series and the terms of the Q-series. The relation we want is

$$P \mathbin{\dot\cup} Q \mathbin{\dot\cup} C'P \uparrow C'Q,$$

since this makes every term of the P-series precede every term of the Q-series. Hence we put

$$P \mathbin{\updownarrow} Q = P \mathbin{\dot\cup} Q \mathbin{\dot\cup} C'P \uparrow C'Q \quad \text{Df.}$$

It will be seen that $P \mathbin{\updownarrow} Q$ is in general different from $Q \mathbin{\updownarrow} P$.

If $C'P$ and $C'Q$ have no common terms, the sum of the relation-numbers of P and Q is the relation-number of $P \mathbin{\updownarrow} Q$ (cf. $*180$).

The addition of a single term to a series requires a new definition, and cannot be dealt with as a particular case of the addition of two relations. It might be thought that, just as $\alpha \cup \iota'x$ gives the result of adding the one term x to the class α, so $P \mathbin{\updownarrow} (x \downarrow x)$ would give the result of adding the one term x to the series P. But this is not the case, since, when we add a term to a series, we do not want this term to precede itself, whereas $P \mathbin{\updownarrow} (x \downarrow x)$ is a relation which x has to itself. What we want is a relation which every member of $C'P$ has to x but which x does not have to itself; thus we take $P \mathbin{\dot\cup} C'P \uparrow \iota'x$ as our relation, and put

$$P \mathbin{+\!\!\!\rightarrow} x = P \mathbin{\dot\cup} C'P \uparrow \iota'x \quad \text{Df.}$$

This definition defines the generating relation of the series obtained by adding x at the *end* of the P-series; similarly for adding x at the *beginning* we put

$$x \mathbin{\leftarrow\!\!\!+} P = \iota'x \uparrow C'P \mathbin{\dot\cup} P \quad \text{Df.}$$

If x is not a member of $C'P$, the relation-number of $P \rightarrow\!\!\!\!+ x$ is the sum of the relation-number of P and the ordinal 1, which we represent by $\dot{1}$. (The ordinal 1 has no meaning by itself, but only as a summand.)

The sum of a series of series is defined in the same way as the sum of two series was defined. Let P be a serial relation whose field consists of serial relations. Then the sum of all the series generated by members of $C'P$, when these series are taken in the order generated by P, must be a relation which holds between x and y whenever either (1) x and y both belong to the field of one of the series, and x precedes y in this series, or (2) x belongs to the field of an earlier series than that to which y belongs. In the first case, we have $(\exists Q) . Q \epsilon C'P . xQy$, *i.e.* $x (\dot{s}'C'P) y$. In the second case, we have $(\exists Q, R) . QPR . x \epsilon C'Q . y \epsilon C'R$, *i.e.* $(\exists Q, R) . QPR . xFQ . yFR$, *i.e.* $x (F ; P) y$. Hence the generating relation of the sum of all the series is $\dot{s}'C'P \cup F ; P$. Hence we put

$$\Sigma'P = \dot{s}'C'P \cup F ; P \quad \text{Df.}$$

The relation $\Sigma'P$ has all the properties which we should expect of the sum of a series of series.

If a series is to result from the addition of a series of series, it is necessary that no two of the series should have any common terms. For if we have

$$QPR . x \epsilon C'Q \cap C'R,$$

we shall also have $$x (\Sigma'P) x.$$

Hence instead of a series, we shall have cycles; for it is essential to a series that no term should precede itself. (What seem to be series in which there is repetition are always the result of a one-many correlation with series in which there is no repetition, so that a term can be counted once as the correlate of one term, and again as the correlate of a later term.) For this reason, as well as for many others, it is important to consider relations between mutually exclusive relations, *i.e.* between relations whose fields have no common terms. We put

$$\text{Rel}^2 \text{excl} = \hat{P} \{Q, R \epsilon C'P . Q \neq R . \supset_{Q,R} . C'Q \cap C'R = \Lambda\} \quad \text{Df.}$$

Then Rel^2 excl has much the same utility in relation-arithmetic as Cls^2 excl has in cardinal arithmetic. We have

$$\vdash : P \epsilon \text{Rel}^2 \text{excl} . \equiv . F \upharpoonright C'P \epsilon \text{Cls} \rightarrow 1,$$

which is analogous to the proposition (∗84·14)

$$\vdash : \kappa \epsilon \text{Cls}^2 \text{excl} . \equiv . \epsilon \upharpoonright \kappa \epsilon \text{Cls} \rightarrow 1.$$

It will be found that in relation-arithmetic the relation F often appears where ϵ appears in the analogous proposition of cardinal arithmetic.

Analogous to "sm sm" is the relation of double ordinal similarity. This holds between two relations P and Q when they are ordinally similar relations between ordinally similar relations with known correlators, *i.e.* when, if T is

an ordinal correlator of P and Q, so that $P = T ; Q$, then if X is a member of $C`P$, and $Y$ is the corresponding member of $C`Q$, so that XTY, we shall have X smor Y, and shall be able to specify a member of $X\,\overline{\text{smor}}\,Y$. But as in cardinals, so here, we have to frame our definition of double ordinal similarity in such a way as to minimize the use of the multiplicative axiom. We therefore take as our definition the following: P and Q are said to have donble ordinal similarity when there is a one-one relation S which has $C`\Sigma`Q$ for its converse domain, and is such that $P = S\dagger ; Q$. A relation S which has these properties is called a *double correlator* of P and Q, *i.e.* we put

$$P\,\overline{\text{smor}}\,\overline{\text{smor}}\,Q = (1 \to 1) \cap \overleftarrow{\text{Cl}}`C`\Sigma`Q \cap \hat{S}(P = S\dagger ; Q) \quad \text{Df},$$

a definition which, as will be perceived, is closely analogous to that of $\kappa\,\overline{\text{sm}}\,\overline{\text{sm}}\,\lambda$ in $*111$. Two relations have double similarity when they have a double correlator, *i.e.*

$$\text{smor smor} = \hat{P}\hat{Q}\,\{\exists\,!\,P\,\overline{\text{smor}}\,\overline{\text{smor}}\,Q\} \quad \text{Df.}$$

S is a double correlator of P and Q when S is a correlator of $\Sigma`P$ and $\Sigma`Q$ and $S\dagger \restriction C`Q$ is a correlator of P and Q. This might be taken as the definition of a double correlator, since it is equivalent to the above definition.

If we assume the multiplicative axiom, we can prove that double similarity holds between similar relations of mutually exclusive similar relations, *i.e.* between two relations of mutually exclusive relations P and Q which have a correlator S such that, if $Y \in C`Q$, then $Y$ and $S`Y$ are always similar. In this case, $S \subset$ smor. Thus if we assume the multiplicative axiom we have, if $P, Q \in \text{Rel}^2\text{excl}$,

$$P\,\text{smor smor}\,Q \,.\equiv.\, \exists\,!\,P\,\overline{\text{smor}}\,Q \cap \text{Rl}`\text{smor}.$$

In the particular case in which the fields of P and Q consist of *well-ordered* relations (*i.e.* relations generating well-ordered series), this equivalence can be proved without the use of the multiplicative axiom, because two similar well-ordered relations have only one correlator, so that the difficulty of selecting among correlators does not arise.

Double ordinal correlators have the same importance in proving the formal laws of relation-arithmetic that double cardinal correlators have in cardinal arithmetic. The construction of double correlators in various cases constitutes a large part of relation-arithmetic.

In defining the ordinal product of two relation-numbers, and in defining exponentiation, we use a relation which has properties analogous to those of $\alpha \underset{\prime\prime}{\downarrow} ``\beta$. This relation is $P \underset{;}{\downarrow} ; Q$, of which the structure is as follows: Let z, w be two terms having the relation Q; then form the two relations $\downarrow z ; P$, $\downarrow w ; P$. The relation $\downarrow z ; P$ holds between two couples $x \downarrow z$ and $y \downarrow z$ whenever xPy; thus it arranges couples whose referents are members of $C`P$, and whose relata are z, in an order similar to P. The relations $\downarrow z ; P$ and $\downarrow w ; P$

are (by $*150{\cdot}03$) the same as $P \underset{\cdot\cdot}{\downarrow} z$ and $P \underset{\cdot\cdot}{\downarrow} w$. Thus $P \underset{\cdot\cdot}{\downarrow} {}^{;}Q$ arranges such relations as $\downarrow z{}^{;}P$ in an order similar to Q. Thus $P \underset{\cdot\cdot}{\downarrow} {}^{;}Q$ is similar to Q, and every member of its field is similar to P. Thus the relation-number of $P \underset{\cdot\cdot}{\downarrow} {}^{;}Q$ is $\mathrm{Nr}{}^{\backprime}Q$, and every member of its field has the relation-number $\mathrm{Nr}{}^{\backprime}P$. Moreover $P \underset{\cdot\cdot}{\downarrow} {}^{;}Q$, as it is easy to see, is a relation of mutually exclusive relations. Hence it is suitable for defining the product of Q and P, and we put

$$Q \times P = \Sigma{}^{\backprime}P \underset{\cdot\cdot}{\downarrow} {}^{;}Q \quad \text{Df.}$$

In the next section, after we have defined the product of a relation of relations, we shall use the same relation $P \underset{\cdot\cdot}{\downarrow} {}^{;}Q$ for the definition of exponentiation, putting

$$P \exp Q = \mathrm{Prod}{}^{\backprime}P \underset{\cdot\cdot}{\downarrow} {}^{;}Q \quad \text{Df.}$$

These two definitions should be compared with those in $*113$ and $*116$.

In virtue of the definition of Σ, the relation $\Sigma{}^{\backprime}P \underset{\cdot\cdot}{\downarrow} {}^{;}Q$ holds between terms which either have one of the relations of the form $P \underset{\cdot\cdot}{\downarrow} z$, or belong respectively to the fields of two relations $P \underset{\cdot\cdot}{\downarrow} z$, $P \underset{\cdot\cdot}{\downarrow} w$, where zQw. Thus the relation $\Sigma{}^{\backprime}P \underset{\cdot\cdot}{\downarrow} {}^{;}Q$ holds between $x \downarrow z$ and $y \downarrow z$ whenever xPy and $z \in C{}^{\backprime}Q$, and also between $x \downarrow z$ and $y \downarrow w$ whenever $x, y \in C{}^{\backprime}P \,.\, zQw$. Thus if, for the sake of illustration, P and Q generate finite series, so that their fields are

$$1_P, 2_P, \ldots, \mu_P,$$
$$1_Q, 2_Q, \ldots, \nu_Q,$$

then the field of $\Sigma{}^{\backprime}P \underset{\cdot\cdot}{\downarrow} {}^{;}Q$ will consist of the couples

$$1_P \downarrow 1_Q,\ 2_P \downarrow 1_Q,\ \ldots,\ \mu_P \downarrow 1_Q;$$
$$1_P \downarrow 2_Q,\ 2_P \downarrow 2_Q,\ \ldots,\ \mu_P \downarrow 2_Q;$$
$$\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots$$
$$1_P \downarrow \nu_Q,\ 2_P \downarrow \nu_Q,\ \ldots,\ \mu_P \downarrow \nu_Q;$$

and their order as arranged by $\Sigma{}^{\backprime}P \underset{\cdot\cdot}{\downarrow} {}^{;}Q$ is that in which they are written above. Thus the above couples in the above order constitute the series $Q \times P$, and it is evident that this series has $\nu \times \mu$ terms.

When the factors of a product are not enumerated, but are given as the field of a relation, a new definition of multiplication is required. This definition, which has the advantage of being applicable to infinite products, will be dealt with in the following section.

$*160$. THE SUM OF TWO RELATIONS

Summary of $*160$.

In this number, we introduce the definition

$$P \mathbin{\stackrel{\uparrow}{+}} Q = P \cup Q \cup C\text{‘}P \uparrow C\text{‘}Q \quad \text{Df},$$

which was explained in the introduction to this section. Although the propositions of this and other numbers in this Part do not require that P and Q should be such as to generate series, yet the reader will find it convenient to imagine them to be such, since the important applications of the ideas of this Part are to series. Thus we may regard the sum of P and Q as a relation which holds between x and y when either x precedes y in the P-series, or x precedes y in the Q-series, or x belongs to the P-series and y belongs to the Q-series.

The most important propositions of this number are:

$*160{\cdot}14$. $\vdash . C\text{‘}(P \mathbin{\stackrel{\uparrow}{+}} Q) = C\text{‘}P \cup C\text{‘}Q$

$*160{\cdot}21$. $\vdash . P \mathbin{\stackrel{\uparrow}{+}} \dot{\Lambda} = P$

$*160{\cdot}22$. $\vdash . \dot{\Lambda} \mathbin{\stackrel{\uparrow}{+}} Q = Q$

$*160{\cdot}31$. $\vdash . (P \mathbin{\stackrel{\uparrow}{+}} Q) \mathbin{\stackrel{\uparrow}{+}} R = P \mathbin{\stackrel{\uparrow}{+}} (Q \mathbin{\stackrel{\uparrow}{+}} R)$

which is the associative law, and

$*160{\cdot}4$. $\vdash . (P \cup Q) \mathbin{\stackrel{\uparrow}{+}} R = (P \mathbin{\stackrel{\uparrow}{+}} R) \cup (Q \mathbin{\stackrel{\uparrow}{+}} R)$

which is the distributive law for logical and arithmetical addition;

$*160{\cdot}44$. $\vdash : C\text{‘}P \subset \text{Ɑ}\text{‘}S . C\text{‘}Q \subset \text{Ɑ}\text{‘}S . \supset . S\text{⁏}(P \mathbin{\stackrel{\uparrow}{+}} Q) = S\text{⁏}P \mathbin{\stackrel{\uparrow}{+}} S\text{⁏}Q$

which is also a kind of distributive law;

$*160{\cdot}47$. $\vdash : C\text{‘}P \cap C\text{‘}Q = \Lambda . C\text{‘}P' \cap C\text{‘}Q' = \Lambda . S \in P \,\overline{\text{smor}}\, P' . T \in Q \,\overline{\text{smor}}\, Q' . \supset .$
$S \cup T \in (P \mathbin{\stackrel{\uparrow}{+}} Q) \,\overline{\text{smor}}\, (P' \mathbin{\stackrel{\uparrow}{+}} Q')$

whence

$*160{\cdot}48$. $\vdash : C\text{‘}P \cap C\text{‘}Q = \Lambda . C\text{‘}P' \cap C\text{‘}Q' = \Lambda . P \,\text{smor}\, P' . Q \,\text{smor}\, Q' . \supset .$
$P \mathbin{\stackrel{\uparrow}{+}} Q \,\text{smor}\, P' \mathbin{\stackrel{\uparrow}{+}} Q'$

whence it follows that if P and Q are mutually exclusive, the relation-number of their sum depends only upon the relation-numbers of P and Q;

$*160{\cdot}5$. $\vdash : C\text{‘}P \cap C\text{‘}Q = \Lambda . \supset . (P \mathbin{\stackrel{\uparrow}{+}} Q) \upharpoonright C\text{‘}P = P . (P \mathbin{\stackrel{\uparrow}{+}} Q) \upharpoonright C\text{‘}Q = Q$

$*160{\cdot}52$. $\vdash : C\text{‘}P \cap C\text{‘}Q = \Lambda . C\text{‘}P \cap C\text{‘}R = \Lambda . P \mathbin{\stackrel{\uparrow}{+}} Q = P \mathbin{\stackrel{\uparrow}{+}} R . \supset . Q = R$

$*160{\cdot}01$. $P \mathbin{\stackrel{\uparrow}{+}} Q = P \cup Q \cup C\text{‘}P \uparrow C\text{‘}Q \quad \text{Df}$

$*160{\cdot}1$. $\vdash . P \mathbin{\stackrel{\uparrow}{+}} Q = P \cup Q \cup C\text{‘}P \uparrow C\text{‘}Q$ $\quad$ [($*160{\cdot}01$)]

$*160{\cdot}11$. $\vdash :. x (P \mathbin{\stackrel{\uparrow}{+}} Q) y . \equiv : xPy . \vee . xQy . \vee . x \in C\text{‘}P . y \in C\text{‘}Q$ $\quad$ [$*160{\cdot}1$]

$*160{\cdot}111$. $\vdash :. x (P \mathbin{\stackrel{\uparrow}{+}} Q) y . \equiv : xPy . \vee . xQy . \vee . xFP . yFQ$ $\quad$ [$*160{\cdot}11 . *33{\cdot}51$]

$*160{\cdot}12.\ \vdash : \dot{\exists} ! Q . \supset . \mathrm{D}`(P \dotplus Q) = C`P \cup \mathrm{D}`Q \quad [*33{\cdot}26 . *35{\cdot}85 . *160{\cdot}1]$

$*160{\cdot}13.\ \vdash : \dot{\exists} ! P . \supset . \mathrm{G}`(P \dotplus Q) = \mathrm{G}`P \cup C`Q$

$*160{\cdot}14.\ \vdash . C`(P \dotplus Q) = C`P \cup C`Q$

Dem.

$\vdash . *33{\cdot}262 . *160{\cdot}1 . \supset \vdash . C`(P \dotplus Q) = C`P \cup C`Q \cup C`(C`P \uparrow C`Q) \quad (1)$

$[\mathrm{Hp}] \qquad \supset \,.\, Q = R : \supset \vdash \,.\, \mathrm{Prop}$

The above proposition is used in dealing with the series of segments of a series ($*213{\cdot}561$).

$*161$. ADDITION OF A TERM TO A RELATION

Summary of $*161$.

The addition of a term has two forms, according as it occurs at the beginning or end of the field of the relation in question. If we add first x and then y at the end, the result is the same as if we added $x \downarrow y$ ($*161\cdot22$); if at the beginning, it is the same as if we added $y \downarrow x$ ($*161\cdot221$). The propositions of the present number are all obvious, and offer no difficulties of any kind. As explained in the introduction to this section, we put

$$P \rightarrow\!\!\!\!\!+\, x = P \cup C\text{‘}P \uparrow \iota\text{‘}x \quad \text{Df},$$

$$x \,+\!\!\!\!\!\leftarrow P = \iota\text{‘}x \uparrow C\text{‘}P \cup P \quad \text{Df}.$$

Most of the propositions of this number require the hypothesis $\dot{\exists}\,!\,P$, because if $P = \dot{\Lambda}$, $P \rightarrow\!\!\!\!\!+\, x = x \,+\!\!\!\!\!\leftarrow P = \dot{\Lambda}$ ($*161\cdot2\cdot201$). This is connected with the fact that there is no ordinal number 1. Apart from propositions already mentioned, the chief propositions of this number are the following (we omit propositions about $x \,+\!\!\!\!\!\leftarrow P$ when they are merely analogues of propositions about $P \rightarrow\!\!\!\!\!+\, x$):

$*161\cdot12$. $\vdash . x \,+\!\!\!\!\!\leftarrow P = \text{Cnv}\text{‘}(\breve{P} \rightarrow\!\!\!\!\!+\, x)$

$*161\cdot14$. $\vdash :\dot{\exists}\,!\,P . \supset . C\text{‘}(P \rightarrow\!\!\!\!\!+\, x) = C\text{‘}P \cup \iota\text{‘}x = C\text{‘}(x \,+\!\!\!\!\!\leftarrow P)$

$*161\cdot15$. $\vdash :\dot{\exists}\,!\,P . x \sim\in C\text{‘}P . \supset .$

$$\overrightarrow{B}\text{‘}(P \rightarrow\!\!\!\!\!+\, x) = \overrightarrow{B}\text{‘}P . \overrightarrow{B}\text{‘}\text{Cnv}\text{‘}(P \rightarrow\!\!\!\!\!+\, x) = \iota\text{‘}x . B\text{‘}(x \,+\!\!\!\!\!\leftarrow \breve{P}) = x$$

$*161\cdot211$. $\vdash . x \,+\!\!\!\!\!\leftarrow (y \downarrow z) = x \downarrow y \cup x \downarrow z \cup y \downarrow z = (x \downarrow y) \rightarrow\!\!\!\!\!+\, z$

$*161\cdot31$. $\vdash : P \,\text{smor}\, Q . x \sim\in C\text{‘}P . y \sim\in C\text{‘}Q . \supset .$

$$P \rightarrow\!\!\!\!\!+\, x \,\text{smor}\, Q \rightarrow\!\!\!\!\!+\, y . x \,+\!\!\!\!\!\leftarrow P \,\text{smor}\, y \,+\!\!\!\!\!\leftarrow Q$$

$*161\cdot4$. $\vdash : C\text{‘}Q \subset \text{Ɑ}\text{‘}S . x \in \text{Ɑ}\text{‘}S . S \in 1 \rightarrow \text{Cls} . \supset . S;(Q \rightarrow\!\!\!\!\!+\, x) = S;Q \rightarrow\!\!\!\!\!+\, S\text{‘}x$

$*161\cdot01$. $P \rightarrow\!\!\!\!\!+\, x = P \cup C\text{‘}P \uparrow \iota\text{‘}x \quad \text{Df}$

$*161\cdot02$. $x \,+\!\!\!\!\!\leftarrow P = \iota\text{‘}x \uparrow C\text{‘}P \cup P \quad \text{Df}$

$*161\cdot1$. $\vdash . P \rightarrow\!\!\!\!\!+\, x = P \cup C\text{‘}P \uparrow \iota\text{‘}x$ [($*161\cdot01$)]

$*161\cdot101$. $\vdash . x \,+\!\!\!\!\!\leftarrow P = \iota\text{‘}x \uparrow C\text{‘}P \cup P$ [($*161\cdot02$)]

$*161\cdot11$. $\vdash :. y (P \rightarrow\!\!\!\!\!+\, x) z . \equiv : yPz . \vee . y \in C\text{‘}P . z = x$ [$*161\cdot1$]

$*161\cdot111$. $\vdash :. y (x \,+\!\!\!\!\!\leftarrow P) z . \equiv : y = x . z \in C\text{‘}P . \vee . yPz$ [$*161\cdot101$]

$*161\cdot12$. $\vdash . x \,+\!\!\!\!\!\leftarrow P = \text{Cnv}\text{‘}(\breve{P} \rightarrow\!\!\!\!\!+\, x)$ [$*161\cdot1\cdot101 . *35\cdot84 . *33\cdot22$]

***161·13.** $\vdash . \mathrm{D}'(P \mathbin{+\!\!\!\rightarrow} x) = C'P . \text{Ɑ}'(x \mathbin{\leftarrow\!\!\!+} P) = C'P$

Dem.

$\vdash . *161·1 . \supset \vdash . \mathrm{D}'(P \mathbin{+\!\!\!\rightarrow} x) = \mathrm{D}'P \cup \mathrm{D}'(C'P \uparrow \iota'x)$

$[*35·85] \qquad = \mathrm{D}'P \cup C'P$

$[*33·161] \qquad = C'P \qquad (1)$

Similarly $\quad \vdash . \text{Ɑ}'(x \mathbin{\leftarrow\!\!\!+} P) = C'P \qquad (2)$

$\vdash . (1) . (2) . \supset \vdash .$ Prop

***161·131.** $\vdash : \dot{\exists} ! P . \supset . \text{Ɑ}'(P \mathbin{+\!\!\!\rightarrow} x) = \text{Ɑ}'P \cup \iota'x . \mathrm{D}'(x \mathbin{\leftarrow\!\!\!+} P) = \mathrm{D}'P \cup \iota'x$

[*35·86 . *161·1]

***161·14.** $\vdash : \dot{\exists} ! P . \supset . C'(P \mathbin{+\!\!\!\rightarrow} x) = C'P \cup \iota'x = C'(x \mathbin{\leftarrow\!\!\!+} P)$ [*161·13·131]

The hypothesis $\dot{\exists} ! P$ is necessary in this proposition, since without it we have $P \mathbin{+\!\!\!\rightarrow} x = \dot{\Lambda}$.

***161·141.** $\vdash : \dot{\exists} ! P . \supset . \overrightarrow{B}'(P \mathbin{+\!\!\!\rightarrow} x) = \overrightarrow{B}'P - \iota'x . \overrightarrow{B}'\mathrm{Cnv}'(P \mathbin{+\!\!\!\rightarrow} x) = \iota'x - C'P$

[*161·13·131 . *93·101]

***161·15.** $\vdash : \dot{\exists} ! P . x \sim \epsilon\, C'P . \supset .$

$\overrightarrow{B}'(P \mathbin{+\!\!\!\rightarrow} x) = \overrightarrow{B}'P . \overrightarrow{B}'\mathrm{Cnv}'(P \mathbin{+\!\!\!\rightarrow} x) = \iota'x . B'(x \mathbin{\leftarrow\!\!\!+} \breve{P}) = x$ [*161·141]

***161·16.** $\vdash : x \sim \epsilon\, C'P . \supset . (P \mathbin{+\!\!\!\rightarrow} x) \upharpoonright C'P = (P \mathbin{+\!\!\!\rightarrow} x) \upharpoonright (-\iota'x) = P$ [*161·1]

The above proposition is used in the theory of connected relations (*202·412).

***161·161.** $\vdash : x \sim \epsilon\, C'P . \supset . (x \mathbin{\leftarrow\!\!\!+} P) \upharpoonright C'P = (x \mathbin{\leftarrow\!\!\!+} P) \upharpoonright (-\iota'x) = P$

The two following propositions are frequently used.

***161·2.** $\vdash . \dot{\Lambda} \mathbin{+\!\!\!\rightarrow} x = \dot{\Lambda}$ [*35·75·82 . *161·1]

***161·201.** $\vdash . x \mathbin{\leftarrow\!\!\!+} \dot{\Lambda} = \dot{\Lambda}$

***161·21.** $\vdash . (x \downarrow y) \mathbin{+\!\!\!\rightarrow} z = x \downarrow y \mathbin{\dot{\cup}} x \downarrow z \mathbin{\dot{\cup}} y \downarrow z$

Dem.

$\vdash . *161·1 . *55·15 . \supset \vdash . (x \downarrow y) \mathbin{+\!\!\!\rightarrow} z = x \downarrow y \mathbin{\dot{\cup}} (\iota'x \cup \iota'y) \uparrow \iota'z$

$[*35·82·41 . *55·1] \qquad = x \downarrow y \mathbin{\dot{\cup}} x \downarrow z \mathbin{\dot{\cup}} y \downarrow z . \supset \vdash .$ Prop

Note that $x \downarrow y \mathbin{\dot{\cup}} x \downarrow z \mathbin{\dot{\cup}} y \downarrow z$ is the relation which orders x and y and z in the order x, y, z.

***161·211.** $\vdash . x \mathbin{\leftarrow\!\!\!+} (y \downarrow z) = x \downarrow y \mathbin{\dot{\cup}} x \downarrow z \mathbin{\dot{\cup}} y \downarrow z = (x \downarrow y) \mathbin{+\!\!\!\rightarrow} z$

[Proof as in *161·21]

***161·212.** $P \mathbin{+\!\!\!\rightarrow} x \mathbin{+\!\!\!\rightarrow} y = (P \mathbin{+\!\!\!\rightarrow} x) \mathbin{+\!\!\!\rightarrow} y$ Df

***161·213.** $x \mathbin{\leftarrow\!\!\!+} y \mathbin{\leftarrow\!\!\!+} P = x \mathbin{\leftarrow\!\!\!+} (y \mathbin{\leftarrow\!\!\!+} P)$ Df

These definitions serve merely for the avoidance of brackets.

***161·22.** $\vdash : \dot{\exists} ! P . \supset . (P \mathbin{+\!\!\!\rightarrow} x) \mathbin{+\!\!\!\rightarrow} y = P \mathbin{\text{⇞}} (x \downarrow y)$

Dem.

$*$162. THE SUM OF THE RELATIONS OF A FIELD

Summary of $*$162.

The form of summation defined in $*$160 cannot be extended beyond a finite number of summands, since it involves explicit mention of all the summands. In the present number, we shall be concerned with a form of summation which is not subject to this restriction. It will be observed that, since relational summation is not permutative, we cannot define the sum of a *class* of relations, for this would not determine the order in which the summation is to be effected. Our relations must be given as the field of some relation which orders them; thus the sum appears not as the sum of a class, but as the sum of a relation, namely of a relation whose field is the relations to be summed. In the case of two relations Q and R, the sum of $Q \downarrow R$, as defined in the present number, will be equal to $Q \mathbin{\text{⤉}} R$; similarly for three, the sum of $Q \downarrow R \cup Q \downarrow S \cup R \downarrow S$ will be equal to $Q \mathbin{\text{⤉}} R \mathbin{\text{⤉}} S$, and so on for any finite number of summands.

As explained in the introduction to this Section, if P is a relation between relations, we put

$$\Sigma\text{‘}P = \dot{s}\text{‘}C\text{‘}P \cup F\,;P \quad \text{Df.}$$

It is convenient to suppose that P is serial, and that every member of $C\text{‘}P$ is also serial. Then $\Sigma\text{‘}P$ holds between x and y if either (1) there is a series, in the field of P, in which x precedes y, or (2) x belongs to a series which is earlier, in the P-series, than the series to which y belongs. The following are the chief propositions of this number:

$*$162·22·23. $\vdash . C\text{‘}\Sigma\text{‘}P = s\text{‘}C\text{‘‘}C\text{‘}P = C\text{‘}\dot{s}\text{‘}C\text{‘}P = F\text{‘‘}C\text{‘}P = \overrightarrow{F^2}\text{‘}P$

$*$162·26. $\vdash . \Sigma\text{‘}(P \cup Q) = \Sigma\text{‘}P \cup \Sigma\text{‘}Q$

$*$162·3. $\vdash . \Sigma\text{‘}(Q \downarrow R) = Q \mathbin{\text{⤉}} R$

$*$162·31. $\vdash . \Sigma\text{‘}Q \mathbin{\text{⤉}} \Sigma\text{‘}R = \Sigma\text{‘}(Q \mathbin{\text{⤉}} R)$

$*$162·34. $\vdash . \Sigma\text{‘}\Sigma\,;P = \Sigma\text{‘}\Sigma\text{‘}P$ [Associative Law. Cf. $*$42·1.]

$*$162·35. $\vdash : C\text{‘}\Sigma\text{‘}Q \subset \text{Ꮖ}\text{‘}R \,.\supset .\, \Sigma\text{‘}R\dagger\,;Q = R\,;\Sigma\text{‘}Q$

This is the analogue of $*$40·38. (Cf. note to $*$162·35, below.)

$*$162·4. $\vdash . \Sigma\text{‘}\dot{\Lambda} = \dot{\Lambda}$

$*$162·42. $\vdash : \dot{\exists}\,!\,\Sigma\text{‘}P \,.\equiv .\, \dot{\exists}\,!\,\dot{s}\text{‘}C\text{‘}P \,.\equiv .\, \exists\,!\,C\text{‘}P - \iota\text{‘}\dot{\Lambda}$

$*$162·43. $\vdash : \dot{\exists}\,!\,P \,.\supset .\, \Sigma\text{‘}(P \mathbin{+\!\!\!\rightarrow} R) = \Sigma\text{‘}P \mathbin{\text{⤉}} R$

It should be observed that the ordinal analogues of propositions about classes of classes often involve the substitution of Σ (not $\dot{s}$) for s. Examples are afforded by $*$162·34·35, quoted above.

$[*150{\cdot}3 . *162{\cdot}1] \qquad = R;\Sigma'Q : \supset \vdash . \text{Prop}$

This proposition is important, since it enables us to infer (with a suitable hypothesis) that if $R;M$ is always like M when $M \in C'Q$, then the arithmetical sum of all such relations as $R;M$ is like $\Sigma'Q$, being in fact $R;\Sigma'Q$. In other words, if, whenever $M \in C'Q$, $R \upharpoonright C'M$ is a correlator of $R;M$ and M, then $R \upharpoonright \Sigma'Q$ is a correlator of $\Sigma'R\dagger;Q$ and $\Sigma'Q$. This proposition is analogous in its uses to the proposition

$$s'R_\epsilon``\kappa = R``s'\kappa,$$

which is $*40\cdot38$. In general, in obtaining relational analogues of cardinal propositions, $R``\kappa$ is to be replaced by $R;Q$, $R_\epsilon$ by $R\dagger$, and $s$ by $\Sigma$. When these substitutions are made in $s`R_\epsilon``\kappa = R``s`\kappa$, $*162\cdot35$ results, except for its hypothesis.

If we regard $R;Q$ as a kind of product of R and Q, $*162\cdot35$ becomes a distributive law. For it asserts that if we multiply each member of $C`Q$ by $R$, and then sum the resulting products, we get the same relation as if we first sum $C`Q$, and then multiply by R. The following application of $*162\cdot35$ to the sum of two relations makes its distributive character more evident.

The above proposition is used in *174·162.

$*163$. RELATIONS OF MUTUALLY EXCLUSIVE RELATIONS

Summary of $*163$.

In the present number we have to define mutually exclusive relations, and to give a few of their properties. Mutually exclusive relations play much the same part in relation-arithmetic as mutually exclusive classes play in cardinal arithmetic. *Prima facie,* there are various ways in which we might define them. We might define P as a relation of mutually exclusive relations when

$$QPR \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, Q \dot{\cap} R = \dot{\Lambda},$$

or when $$Q, R \in C\text{`}P \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, Q \dot{\cap} R = \dot{\Lambda},$$

or when

$$Q, R \in C\text{`}P \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, \text{D}\text{`}Q \cap \text{D}\text{`}R = \Lambda \,.\, \text{G}\text{`}Q \cap \text{G}\text{`}R = \Lambda,$$

or in several other ways. But in fact the most useful property to choose is the property that any two members of the field have mutually exclusive fields, *i.e.*

$$Q, R \in C\text{`}P \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, C\text{`}Q \cap C\text{`}R = \Lambda.$$

The principal applications of the subjects studied in this Part are to series, and in series it is always the *fields* of the relations that are important. We want, for instance, to define relations of mutually exclusive relations in such a way that, if P is a serial relation, and every member of $C\text{`}P$ is a serial relation, then $\Sigma\text{`}P$ is a serial relation. For this purpose it is necessary that $\Sigma\text{`}P$ should be contained in diversity, which requires that $F;P$ should be contained in diversity, *i.e.* that

$$QPR \,.\, \supset_{Q,R} \,.\, C\text{`}Q \cap C\text{`}R = \Lambda.$$

If P is a serial relation, as we are supposing, this is equivalent to

$$Q, R \in C\text{`}P \,.\, Q \neq P \,.\, \supset_{Q,R} \,.\, C\text{`}Q \cap C\text{`}R = \Lambda.$$

Again we want to define relations of mutually exclusive relations in such a way that, if P and Q are two such relations, and P and Q have double likeness (cf. $*164$), then $\Sigma\text{`}P$ is like $\Sigma\text{`}Q$; *i.e.* if we are given a correlator S of P and Q, and for every M and N which S correlates, we are again given a correlator, then $\Sigma\text{`}P$ is to be like $\Sigma\text{`}Q$. That is, if λ is the class of relations which correlate pairs of relations M and N, where $N \in C\text{`}Q \,.\, MSN$, we want $\dot{s}\text{`}\lambda$ to be a correlator of P and Q. Now this requires that $\dot{s}\text{`}\lambda$ should be a one-one relation, which requires

$$M, M' \in C\text{`}P \,.\, M \neq M' \,.\, \supset_{M,M'} \,.\, \text{D}\text{`}M \cap \text{D}\text{`}M' = \Lambda \,.\, \text{G}\text{`}M \cap \text{G}\text{`}M' = \Lambda.$$

This is secured by

$$M, M' \in C\text{`}P \,.\, M \neq M' \,.\, \supset_{M,M'} \,.\, C\text{`}M \cap C\text{`}M' = \Lambda,$$

but except for special classes of relations it is not secured by

$$MPM' \,.\, \supset_{M,M'} \,.\, C\text{`}M \cap C\text{`}M' = \Lambda,$$

since there may be two relations M and M' which both belong to the field of P, but of which neither has the relation P to the other. Again, the analogy with cardinal arithmetic fails at many points unless, when P is a relation of mutually exclusive relations, $C``C`P$ is a class of mutually exclusive classes. But this is not secured by any of the other possible definitions we have been considering. There are further reasons, connected with the arithmetical product of a relation of relations, for choosing as the definition

$$Q, R \in C`P \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, C`Q \cap C`R = \Lambda.$$

From a technical point of view, the properties of a Cls^2 excl depend mainly upon the fact that when κ is such a class, $\epsilon \upharpoonright \kappa \in \text{Cls} \rightarrow 1$ (*84·14); in like manner the properties of a Rel^2 excl depend upon

$$F \upharpoonright C`P \in \text{Cls} \rightarrow 1,$$

which requires our definition, and is equivalent to it (*163·12). We thus become able to use the propositions of *81 on selections from many-one relations, which would not otherwise be the case.

It should be observed that

$$Q, R \in C`P \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, C`Q \cap C`R = \Lambda$$

is not equivalent to

$$C``C`P \in \text{Cls}^2\,\text{excl},$$

though it implies this. The converse implication will fail if $C`P$ contains two different relations with the same field. *E.g.* take a relation $P$ whose field consists of the four relations $S$, $\breve{S}$, $T$, $\breve{T}$, and suppose $C`S \cap C`T = \Lambda$. Then $C``C`P = \iota`C`S \cup \iota`C`T$, and $C``C`P \in \text{Cls}^2\,\text{excl}$. But unless $S = \breve{S}$ and $T = \breve{T}$ we shall not have

$$Q, R \in C`P \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, C`Q \cap C`R = \Lambda.$$

The property by which we define relations of mutually exclusive relations is a property which only depends on the field, so that we might equally well put

$$(\text{Cl}`\text{Rel})\,\text{excl} = \hat{\lambda}\,\{Q, R \in \lambda \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, C`Q \cap C`R = \Lambda\} \quad \text{Df.}$$

But for our purposes this would be less convenient than the definition of Rel^2 excl.

We thus put

***163·01.** $\text{Rel}^2\,\text{excl} = \hat{P}\,\{Q, R \in C`P \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, C`Q \cap C`R = \Lambda\}$ Df

We have

***163·11.** $\vdash :.\, P \in \text{Rel}^2\,\text{excl} \,.\, \equiv :\, Q, R \in C`P \,.\, \exists !\, C`Q \cap C`R \,.\, \supset_{Q,R} \,.\, Q = R$

***163·12.** $\vdash :\, P \in \text{Rel}^2\,\text{excl} \,.\, \equiv \,.\, F \upharpoonright C`P \in \text{Cls} \rightarrow 1$

***163·17.** $\vdash :\, P \in \text{Rel}^2\,\text{excl} \,.\, \equiv \,.\, C \upharpoonright C`P \in 1 \rightarrow 1 \,.\, C``C`P \in \text{Cls}^2\,\text{excl}$

Any of the above might have been used to define Rel^2 excl. The following propositions are important.

*163·3. $\vdash : Q \epsilon \text{Rel}^2\,\text{excl} \,.\, S \epsilon \text{Cls} \to 1 \,.\, \supset \,.\, S \dagger \dot{;} Q \epsilon \text{Rel}^2\,\text{excl}$

This is the analogue of *84·53.

*163·4·41. $\vdash \,.\, \dot{\Lambda}, P \downarrow P \epsilon \text{Rel}^2\,\text{excl}$

*163·441. $\vdash : P, Q \epsilon \text{Rel}^2\,\text{excl} \,.\, C\text{‘}\Sigma\text{‘}P \cap C\text{‘}\Sigma\text{‘}Q = \Lambda \,.\, \supset \,.\, P \ddagger Q \epsilon \text{Rel}^2\,\text{excl}$

*163·451. $\vdash : P \epsilon \text{Rel}^2\,\text{excl} \,.\, C\text{‘}\Sigma\text{‘}P \cap C\text{‘}R = \Lambda \,.\, \supset \,.\, P \dashrightarrow R \epsilon \text{Rel}^2\,\text{excl}$

---

*163·01. $\text{Rel}^2\,\text{excl} = \hat{P}\{Q, R \epsilon C\text{‘}P \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, C\text{‘}Q \cap C\text{‘}R = \Lambda\}$ Df

*163·1. $\vdash :. P \epsilon \text{Rel}^2\,\text{excl} \,.\, \equiv : Q, R \epsilon C\text{‘}P \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, C\text{‘}Q \cap C\text{‘}R = \Lambda$
[(*163·01)]

*163·11. $\vdash :. P \epsilon \text{Rel}^2\,\text{excl} \,.\, \equiv : Q, R \epsilon C\text{‘}P \,.\, \exists ! \, C\text{‘}Q \cap C\text{‘}R \,.\, \supset_{Q,R} \,.\, Q = R$
[*163·1 . Transp]

*163·12. $\vdash : P \epsilon \text{Rel}^2\,\text{excl} \,.\, \equiv \,.\, F \restriction C\text{‘}P \epsilon \text{Cls} \to 1$ [*163·1 . *74·632]

For many purposes, this proposition gives the most useful equivalent of $P \epsilon \text{Rel}^2\,\text{excl}$.

Instead of the above proof, we may use *74·62, which gives us the result in virtue of *33·5.

*163·13. $\vdash :. P \epsilon \text{Rel}^2\,\text{excl} \,.\, \supset :$

$$Q, R \epsilon C\text{‘}P \,.\, Q \neq R \,.\, \supset_{Q,R} \,.\, \text{D}\text{‘}Q \cap \text{D}\text{‘}R = \Lambda \,.\, \text{Cl}\text{‘}Q \cap \text{Cl}\text{‘}R = \Lambda$$

[*115·1.*33·5] $= \text{Prod}\text{‘}C\text{“}C\text{‘}P : \supset \vdash \,.\, \text{Prop}$

This proposition is important in connection with the multiplication of relations, for we shall define as the product of a relation P (whose field consists of relations) a relation whose field is $\text{D}``F_\Delta`C`P$. Thus by the above proposition, whenever P is a $\text{Rel}^2\,\text{excl}$, the field of its product is the product (in the cardinal sense) of the fields of its field, just as the field of its sum is (by $*162\cdot22$) the sum of the fields of its field.

$*164$. DOUBLE LIKENESS

Summary of $*164$.

The subject of this number is of great importance throughout relation-arithmetic and its applications. Double likeness, or double ordinal similarity, is a relation which is to hold between P and Q when (1) P and Q are like, (2) correlated members of the fields of P and Q are like, with a specific given correlator in each case. (It is necessary, in general, to have a given correlator in each case, to avoid the necessity of the multiplicative axiom for selecting among correlators.) This definition can be somewhat simplified by starting from a relation correlating $\Sigma\text{‘}P$ and $\Sigma\text{‘}Q$. If S is such a correlator, so that

$$S \epsilon 1 \to 1 \,.\, \text{Ɑ‘}S = C\text{‘}\Sigma\text{‘}Q \,.\, \Sigma\text{‘}P = S;\Sigma\text{‘}Q,$$

we want S to be such that it not only correlates the whole of $\Sigma\text{‘}P$ with the whole of $\Sigma\text{‘}Q$, but also correlates each member of $C\text{‘}P$ with the corresponding member of $C\text{‘}Q$, *i.e.* such that, if N is any member of $C\text{‘}Q$, $S;N$ is the corresponding member of $C\text{‘}P$. This requires

$$NQN' \,.\equiv .\, (S;N)\,P\,(S;N'),$$

i.e. writing $S\dagger\text{‘}N$, $S\dagger\text{‘}N'$ in place of $S;N$, $S;N'$, it requires

$$P = S\dagger;Q.$$

When $P = S\dagger;Q$ and $\text{Ɑ‘}S = C\text{‘}\Sigma\text{‘}Q$, we have $\Sigma\text{‘}P = S;\Sigma\text{‘}Q$ by $*162\cdot35$. Hence double likeness will subsist if there is a relation S such that

$$S \epsilon 1 \to 1 \,.\, \text{Ɑ‘}S = C\text{‘}\Sigma\text{‘}Q \,.\, P = S\dagger;Q.$$

A relation S fulfilling this condition will be called a *double correlator* of P and Q. Thus two relations P and Q have double likeness when there exists a double correlator of P and Q, *i.e.* when

$$(\exists S) \,.\, S \epsilon 1 \to 1 \,.\, \text{Ɑ‘}S = C\text{‘}\Sigma\text{‘}Q \,.\, P = S\dagger;Q.$$

A double correlator of P and Q is a relation S which is a correlator of $\Sigma\text{‘}P$ and $\Sigma\text{‘}Q$ and is such that $S\dagger \upharpoonright C\text{‘}Q$ is a correlator of P and Q.

It will be seen that this definition has the usual analogy to the corresponding definition in cardinals ($*111\cdot01$). The two inverted commas of the cardinal definition are replaced by the semi-colon, and S_ϵ is replaced by $S\dagger$, and $s\text{‘}\lambda$ is replaced by $\Sigma\text{‘}Q$ or $C\text{‘}\Sigma\text{‘}Q$. The propositions of the present number consist largely of analogues of the propositions of $*111$, in accordance with the above substitutions.

If it were not for the difficulty of choice among correlators, we could define two relations as having double likeness when they are like relations of like relations, *i.e.* when, if P and Q are the two relations, they have a correlator S such that, if MSN, then M smor N. In this case, $S \epsilon P \,\overline{\text{smor}}\, Q \cap \text{Rl‘smor}$.

Thus we have to consider the relations of the class $P \,\overline{\mathrm{smor}}\, Q \cap \mathrm{Rl}'\mathrm{smor}$ to the class of double correlators, and we have to consider the relation of the relation "$\exists ! P \,\overline{\mathrm{smor}}\, Q \cap \mathrm{Rl}'\mathrm{smor}$" to the relation of double likeness. The propositions to be proved on this subject in the present number are analogous to the propositions of $*111$. But at a later stage ($*251{\cdot}61$) we shall show that if the field of P consists entirely of relations which generate *well-ordered* series, then the use of the multiplicative axiom ceases to be necessary in identifying double likeness with the relation $\exists ! P \,\overline{\mathrm{smor}}\, Q \cap \mathrm{Rl}'\mathrm{smor}$, the reason being that two well-ordered series can never be correlated in more than one way.

Our definitions are

$*164{\cdot}01$. $P \,\overline{\mathrm{smor}}\,\overline{\mathrm{smor}}\, Q = (1 \rightarrow 1) \cap \overleftarrow{\mathrm{G}}'C'\Sigma'Q \cap \hat{S}(P = S\dagger{};Q)$ Df

$*164{\cdot}02$. $\mathrm{smor\,smor} = \hat{P}\hat{Q}(\exists ! P \,\overline{\mathrm{smor}}\,\overline{\mathrm{smor}}\, Q)$ Df

The principal propositions of this number are

$*164{\cdot}15$. $\vdash : S \in P \,\overline{\mathrm{smor}}\,\overline{\mathrm{smor}}\, Q \, . \equiv . \, S \in \Sigma'P \,\overline{\mathrm{smor}}\, \Sigma'Q \, . \, (S\dagger) \upharpoonright C'Q \in P \,\overline{\mathrm{smor}}\, Q$

whence

$*164{\cdot}151$. $\vdash : P \,\mathrm{smor\,smor}\, Q \, . \supset . \, \Sigma'P \,\mathrm{smor}\, \Sigma'Q \, . \, P \,\mathrm{smor}\, Q$

$*164{\cdot}18$. $\vdash : S \upharpoonright C'\Sigma'Q \in P \,\overline{\mathrm{smor}}\,\overline{\mathrm{smor}}\, Q \, . \equiv .$

$$S \upharpoonright C'\Sigma'Q \in 1 \rightarrow 1 \, . \, C'\Sigma'Q \subset \mathrm{G}'S \, . \, P = S\dagger{};Q$$

This is usually the most convenient proposition when a double correlation has to be proved.

$*164{\cdot}201{\cdot}211{\cdot}221$. Double likeness is reflexive, symmetrical and transitive.

$*164{\cdot}31$. $\vdash : S \in P \,\overline{\mathrm{smor}}\,\overline{\mathrm{smor}}\, Q \, . \equiv . \, S \in (C''C'P) \,\overline{\mathrm{sm}}\,\overline{\mathrm{sm}}\, (C''C'Q) \, . \, P = S\dagger{};Q$

(Cf. note to $*164{\cdot}31$, below.)

We then have a set of propositions ($*164{\cdot}4$ to the end) on the identification of $\exists ! P \,\overline{\mathrm{smor}}\, Q \cap \mathrm{Rl}'\mathrm{smor}$ with double likeness by means of the multiplicative axiom. We have

$*164{\cdot}43$. $\vdash :. \, P, Q \in \mathrm{Rel}^2\,\mathrm{excl} \, . \, S \in P \,\overline{\mathrm{smor}}\, Q \, .$

$$\mu = \hat{\lambda}\{(\exists N) \, . \, N \in C'Q \, . \, \lambda = (S'N) \,\overline{\mathrm{smor}}\, N\} \, . \supset :$$
$$R \in \epsilon_{\Delta}'\mu \, . \supset . \, \dot{s}'\mathrm{D}'R \in P \,\overline{\mathrm{smor}}\,\overline{\mathrm{smor}}\, Q \, . \, S = (\dot{s}'\mathrm{D}'R)\dagger \upharpoonright C'Q$$

That is to say, given that P and Q are like relations of like mutually exclusive relations, if we can pick out one correlator for each pair of correlated members of $C'P$ and $C'Q$, then the sum ($\dot{s}$) of such selected correlators is a double correlator of P and Q. Hence, observing that if S is a double correlator of P and Q, $(S\dagger) \upharpoonright C'Q \in P \,\overline{\mathrm{smor}}\, Q \cap \mathrm{Rl}'\mathrm{smor}$ ($*164{\cdot}15{\cdot}16$), we arrive at

$*164{\cdot}45$. $\vdash :: \mathrm{Mult\,ax} \, . \supset :.$

$$P, Q \in \mathrm{Rel}^2\,\mathrm{excl} \, . \supset : \exists ! P \,\overline{\mathrm{smor}}\, Q \cap \mathrm{Rl}'\mathrm{smor} \, . \equiv . \, P \,\mathrm{smor\,smor}\, Q$$

From $*164{\cdot}43$ we deduce also

***164·46.** $\vdash :.\ \text{Mult ax} \,.\supset:$

$$P, Q \,\epsilon\, \text{Rel}^2\,\text{excl} \,.\, \exists !\, P \,\overline{\text{smor}}\, Q \cap \text{Rl‘smor} \,.\supset.\, \Sigma\text{‘}P \,\text{smor}\, \Sigma\text{‘}Q$$

***164·48.** $\vdash :.\ \text{Mult ax} \,.\supset:\, R, S \,\epsilon\, \text{Rel}^2\,\text{excl} \cap \text{Nr‘}Q \,.\, C\text{‘}R, C\text{‘}S \,\epsilon\, \text{Cl‘Nr‘}P \,.\supset.$

$$R \,\text{smor smor}\, S \,.\, \Sigma\text{‘}R \,\text{smor}\, \Sigma\text{‘}S$$

I.e. in effect, assuming the multiplicative axiom, if two series (Σ‘R and Σ‘S) can each be divided into β sets of α terms (α, β being relation-numbers), then the two series are ordinally similar, and the β sets in the one case have double similarity with the β sets in the other. (Here we have written α, β in place of the Nr‘P and Nr‘Q of the enunciation.)

It is by means of the above propositions that ordinal addition and multiplication are connected, as will appear in *166.

***164·01.** $P \,\overline{\text{smor}}\,\overline{\text{smor}}\, Q = (1 \rightarrow 1) \cap \overleftarrow{\text{Ɑ}}\text{‘}C\text{‘}\Sigma\text{‘}Q \cap \hat{S}(P = S\dagger ; Q)$ Df

This proposition states that when P and Q have double likeness, there is a correlator of P and Q which couples like with like relations; *i.e.* if S is the correlator, then, if MSN, M and N are ordinally similar. The converse of this proposition, namely, that if P and Q have a correlator which couples ordinally similar relations, then P and Q have double likeness, can be proved if the multiplicative axiom is assumed, but not otherwise, except in special cases, such as that of well-ordered series.

The following proposition is used frequently, owing to the fact that, in the cases we are concerned with, double correlators generally have the form $S \upharpoonright C\text{‘}\Sigma\text{‘}Q$, where S is some relation for which we have $(y) . E ! S\text{‘}y$.

The following propositions are concerned in showing that, if P and Q are like relations, and the correlator of P and Q is contained in likeness (*i.e.* correlates relations which have the relation of likeness), a correlator being given for each pair of relations coupled by the correlator of P and Q, then the logical sum of such correlators is a double correlator of P and Q, provided P and Q are relations of mutually exclusive relations. That is, assuming S to be the correlator of P and Q, and assuming that $S'N \,\text{smor}\, N$ whenever $N \epsilon C'Q$, let it be possible to choose one correlator out of the class of correlators $(S'N) \,\overline{\text{smor}}\, N$, for every N which belongs to $C'Q$. That is, assume that it is possible to make a selection from the class of classes of correlators. If μ is such a selection, then $\dot{s}'\mu$ will be a double correlator of P and Q, if $P, Q \epsilon \text{Rel}^2 \,\text{excl}$.

$*165$. RELATIONS OF RELATIONS OF COUPLES

Summary of $*165$.

In the present number, we shall give various propositions concerning the relation $P \underset{\text{;}}{\downarrow} \text{;}Q$, which has the same uses in relation-arithmetic as $\alpha \underset{\text{''}}{\downarrow} \text{``}\beta$ has in cardinal arithmetic. The propositions of this number will be used in the next number to establish the properties of the arithmetical product of two relations Q and P, which is defined as $\Sigma\text{‘}P \underset{\text{;}}{\downarrow} \text{;}Q$. Again in connection with exponentiation the propositions of the present number will be useful, since, after the product of a relation of relations has been defined ($*172$), we shall define exponentiation by means of the definition

$$P \exp Q = \text{Prod}\text{‘}P \underset{\text{;}}{\downarrow} \text{;}Q \quad \text{Df.} \quad (\text{Cf. } *176.)$$

There will also be occasional uses of the propositions of this number throughout the theory of series. The relation $P \underset{\text{;}}{\downarrow} \text{;}Q$ is important because its structure is thoroughly known. It is a $\text{Rel}^2\,\text{excl}$ which consists of $\text{Nr}\text{‘}Q$ relations, each like P ($*165{\cdot}27$); and if $P \,\text{smor}\, P' \,.\, Q \,\text{smor}\, Q'$, we can construct a double correlator of $P \underset{\text{;}}{\downarrow} \text{;}Q$ and $P' \underset{\text{;}}{\downarrow} \text{;}Q'$ without invoking the multiplicative axiom. In fact we have

$*165{\cdot}362$. $\vdash : R \upharpoonright C\text{‘}P' \in P \,\overline{\text{smor}}\, P' \,.\, S \upharpoonright C\text{‘}Q' \in Q \,\overline{\text{smor}}\, Q' \,.\, \supset .$

$$(R \,\|\, \breve{S}) \upharpoonright C\text{‘}\Sigma\text{‘}P' \underset{\text{;}}{\downarrow} \text{;}Q' \in (P \underset{\text{;}}{\downarrow} \text{;}Q) \,\overline{\text{smor}}\, \overline{\text{smor}}\, (P' \underset{\text{;}}{\downarrow} \text{;}Q')$$

This proposition should be compared with $*113{\cdot}127$. In virtue of $*164{\cdot}31$, together with various propositions of $*165$ and $*166$, it will appear that $*165{\cdot}362$ includes $*113{\cdot}127$ as part of what it asserts.

In the present number, we begin with a set of propositions on fields. We have

$*165{\cdot}12$. $\vdash . C\text{‘}P \underset{\text{;}}{\downarrow} \text{;}Q = P \underset{\text{;}}{\downarrow} \text{``}C\text{‘}Q$

$*165{\cdot}13$. $\vdash . C\text{‘}P \underset{\text{;}}{\downarrow} z = \downarrow z\text{``}C\text{‘}P = (C\text{‘}P) \underset{\text{''}}{\downarrow} z$

whence

$*165{\cdot}14$. $\vdash . C\text{``}C\text{‘}P \underset{\text{;}}{\downarrow} \text{;}Q = (C\text{‘}P) \underset{\text{''}}{\downarrow} \text{``}C\text{‘}Q$

which connects the theory of $P \underset{\text{;}}{\downarrow} \text{;}Q$ with that of $\alpha \underset{\text{''}}{\downarrow} \text{``}\beta$ ($*113$ and $*116$). Hence

$*165{\cdot}16$. $\vdash . C\text{‘}\Sigma\text{‘}P \underset{\text{;}}{\downarrow} \text{;}Q = C\text{‘}Q \times C\text{‘}P$

In $*166$, we shall define $Q \times P$ as $\Sigma\text{‘}P \underset{\text{;}}{\downarrow} \text{;}Q$; thus the above will become

$$\vdash . C\text{‘}(Q \times P) = C\text{‘}Q \times C\text{‘}P.$$

We next have a set of propositions concerned with $P \underset{\cdot,}{\downarrow}$ as a relation, and with the circumstances under which we can infer $x = y$ or $P = Q$ from data as to $P \underset{\cdot,}{\downarrow} x$ and $Q \underset{\cdot,}{\downarrow} y$. We have

***165·21.** $\vdash . P \underset{\cdot,}{\downarrow} ; Q \in \mathrm{Rel}^2 \,\mathrm{excl}$

***165·211.** $\vdash : \exists ! \, C`P \underset{\cdot,}{\downarrow} x \cap C`P \underset{\cdot,}{\downarrow} y . \supset . x = y$

***165·22.** $\vdash : \dot{\exists} ! \, P . \supset . P \underset{\cdot,}{\downarrow} \in 1 \rightarrow 1$

We then have various propositions concerning $\dot{\Lambda}$, of which the chief are

***165·241.** $\vdash : Q = \dot{\Lambda} . \supset . P \underset{\cdot,}{\downarrow} ; Q = \dot{\Lambda}$

***165·242.** $\vdash : P = \dot{\Lambda} . \dot{\exists} ! \, Q . \supset . P \underset{\cdot,}{\downarrow} ; Q = \dot{\Lambda} \downarrow \dot{\Lambda}$

We have next four propositions which are constantly used, proving that $P \underset{\cdot,}{\downarrow} ; Q$ consists of $\mathrm{Nr}`Q$ relations each like P. These propositions are

***165·25.** $\vdash : \dot{\exists} ! \, P . \supset . P \underset{\cdot,}{\downarrow} ; Q \,\mathrm{smor}\, Q . (P \underset{\cdot,}{\downarrow}) \upharpoonright C`Q \in (P \underset{\cdot,}{\downarrow} ; Q) \,\overline{\mathrm{smor}}\, Q$

***165·251.** $\vdash . P \underset{\cdot,}{\downarrow} x \,\mathrm{smor}\, P . (\downarrow x) \upharpoonright C`P \in (P \underset{\cdot,}{\downarrow} x) \,\overline{\mathrm{smor}}\, P$

***165·26.** $\vdash . C`P \underset{\cdot,}{\downarrow} ; Q \subset \mathrm{Nr}`P$

***165·27.** $\vdash : \dot{\exists} ! \, P . \supset . P \underset{\cdot,}{\downarrow} ; Q \in \mathrm{Rel}^2 \,\mathrm{excl} \cap \mathrm{Nr}`Q . C`P \underset{\cdot,}{\downarrow} ; Q \in \mathrm{Cl}`\mathrm{Nr}`P$

From *165·3 to *165·372, we are concerned with constructing a double correlator of $P \underset{\cdot,}{\downarrow} ; Q$ and $P' \underset{\cdot,}{\downarrow} ; Q'$ when we are given simple correlators of P with P' and of Q with Q'. The result (*165·362) has already been given. Hence we have

***165·37.** $\vdash : P \,\mathrm{smor}\, P' . Q \,\mathrm{smor}\, Q' . \supset . P \underset{\cdot,}{\downarrow} ; Q \,\mathrm{smor \, smor}\, P' \underset{\cdot,}{\downarrow} ; Q'$

and by *164·48 and *165·27 we have

***165·38.** $\vdash :. \mathrm{Mult\,ax} . \supset :$

$$R \in \mathrm{Rel}^2 \,\mathrm{excl} \cap \mathrm{Nr}`Q . C`R \subset \mathrm{Nr}`P . \supset . R \,\mathrm{smor\,smor}\, P \underset{\cdot,}{\downarrow} ; Q$$

Hence propositions concerning a series of β series, each containing α terms (where α and β are relation-numbers), which in general require the multiplicative axiom, can be deduced, assuming that axiom, from propositions (not requiring the axiom) concerning $P \underset{\cdot,}{\downarrow} ; Q$, where $\mathrm{Nr}`P = \alpha$ and $\mathrm{Nr}`Q = \beta$. Thus the use of $P \underset{\cdot,}{\downarrow} ; Q$ enables us to minimize the use of the multiplicative axiom.

***165·01.** $\vdash . P \underset{\cdot,}{\downarrow} z = \downarrow z ; P$ [*150·6]

***165·1.** $\vdash : R \, (P \underset{\cdot,}{\downarrow} ; Q) \, S . \equiv . (\exists z, w) . zQw . R = \downarrow z ; P . S = \downarrow w ; P$ [*150·62]

The following propositions are concerned in proving that, if R is a correlator of P and P', and S is a correlator of Q and Q', then $R \| \breve{S}$ (with its converse domain limited) is a double correlator of $P \underset{;}{\downarrow} ;Q$ and $P' \underset{;}{\downarrow} ;Q'$. This proposition is required subsequently in establishing likenesses.

$*166$. THE PRODUCT OF TWO RELATIONS

Summary of $*166$.

The product $Q \times P$ is defined as $\Sigma`P \underset{\bullet}{\downarrow} ;Q$. This is a relation which has for its field all the couples that can be formed by choosing the referent in $C`P$ and the relatum in $C`Q$. These couples are arranged by $Q \times P$ on the following principle: If the relatum of the one couple has the relation Q to the relatum of the other, we put the one before the other, and if the relata of the two couples are equal while the referent of the one has the relation P to the referent of the other, we put the one before the other. Thus in advancing from any term $x \downarrow y$ in the field of $Q \times P$, we first keep y fixed and alter x into later terms as long as possible; then we alter y into a later term, move x back to the beginning, and so on. Thus with a given y, we get a series which is like P, and this series is wholly followed or wholly preceded by the series with the referent y', where y' follows or precedes y.

The propositions of this number are for the most part immediate consequences of those of $*165$. The most important of them are:

$*166{\cdot}12$. $\vdash . C`(P \times Q) = C`P \times C`Q$

$*166{\cdot}13$. $\vdash :. P \times Q = \dot{\Lambda} . \equiv : P = \dot{\Lambda} . \vee . Q = \dot{\Lambda}$

Hence it follows that an ordinal product of a finite number of factors vanishes when, and only when, one of its factors vanishes.

$*166{\cdot}16$. $\vdash . \overrightarrow{B}`(P \times Q) = \overrightarrow{B}`P \times \overrightarrow{B}`Q . \overrightarrow{B}`\mathrm{Cnv}`(P \times Q) = \overrightarrow{B}`\breve{P} \times \overrightarrow{B}`\breve{Q}$

$*166{\cdot}23$. $\vdash : P \,\mathrm{smor}\, P' . Q \,\mathrm{smor}\, Q' . \supset . Q \times P \,\mathrm{smor}\, Q' \times P'$

This proposition shows that the relation-number of a product $Q \times P$ depends only upon the relation-numbers of its factors.

$*166{\cdot}24$. $\vdash :. \mathrm{Mult\,ax} . \supset : R \in \mathrm{Rel}^2\,\mathrm{excl} \cap \mathrm{Nr}`Q . C`R \subset \mathrm{Nr}`P . \supset .$
$$\Sigma`R \,\mathrm{smor}\, Q \times P$$

This proposition connects addition and multiplication (cf. note to $*166{\cdot}24$, below).

$*166{\cdot}42$. $\vdash . (P \times Q) \times R \,\mathrm{smor}\, P \times (Q \times R)$

This is the associative law. The distributive law has two forms:

$*166{\cdot}44$. $\vdash . \Sigma` \times P ;Q = (\Sigma`Q) \times P$

$*166{\cdot}45$. $\vdash . (Q \dotplus R) \times P = (Q \times P) \dotplus (R \times P)$

We do not have in general (cf. note before $*166{\cdot}44$, below)
$$P \times (Q \dotplus R) = (P \times Q) \dotplus (P \times R).$$

We have also a distributive law for the addition of a single term, *i.e.*

$*166{\cdot}53.\ \vdash : \dot{\exists} ! Q . \supset . (Q \dashv\!\!\rightarrow y) \times P = (Q \times P) \ddagger (P \underset{\bullet}{\downarrow} y)$

$*166{\cdot}531.\ \vdash : \dot{\exists} ! Q . \supset . (y \leftarrow\!\!\vdash Q) \times P = (P \underset{\bullet}{\downarrow} y) \ddagger (Q \times P)$

Here again the law does not hold in general for $P \times (Q \dashv\!\!\rightarrow y)$ or $P \times (y \leftarrow\!\!\vdash Q)$.

$*166{\cdot}01.\ Q \times P = \Sigma\text{`}P \underset{\bullet}{\downarrow} ;Q$ Df

[*93·103] $\equiv : (\exists x, z) . x \in \overrightarrow{B}\text{`}P . y \in \overrightarrow{B}\text{`}Q . M = z \downarrow x :$

[*113·101] $\equiv : M \in \overrightarrow{B}\text{`}P \times \overrightarrow{B}\text{`}Q$ (1)

$\vdash . (1) . *166{\cdot}15 . \supset \vdash . \overrightarrow{B}\text{`}\mathrm{Cnv}\text{`}(P \times Q) = \overrightarrow{B}\text{`}\breve{P} \times \overrightarrow{B}\text{`}\breve{Q}$ (2)

$\vdash . (1) . (2) . \supset \vdash .$ Prop

The above proposition is used in the ordinal theory of progressions (*263·62·65).

$*166{\cdot}2.\ \vdash : R \upharpoonright C\text{`}P' \in P \,\overline{\mathrm{smor}}\, P' . \supset . (R \| ) \upharpoonright C\text{`}(Q \times P') \in (Q \times P) \,\overline{\mathrm{smor}}\, (Q \times P')$
[*165·36 . *166·1 . *164·14]

$*166\cdot21.\ \vdash : S \upharpoonright C`Q' \in Q \,\overline{\text{smor}}\, Q' . \supset . (|\breve{S}) \upharpoonright C`(Q' \times P) \in (Q \times P) \,\overline{\text{smor}}\, (Q' \times P)$
[$*165\cdot361 . *166\cdot1 . *164\cdot14$]

$*166\cdot22.\ \vdash : R \upharpoonright C`P' \in P \,\overline{\text{smor}}\, P' . S \upharpoonright C`Q' \in Q \,\overline{\text{smor}}\, Q' . \supset .$
$(R \,\|\, \breve{S}) \upharpoonright C`(Q' \times P') \in (Q \times P) \,\overline{\text{smor}}\, (Q' \times P')$
[$*165\cdot362 . *166\cdot1 . *164\cdot14$]

This proposition gives the correlator for the product when correlators are given for the factors.

$*166\cdot23.\ \vdash : P \text{ smor } P' . Q \text{ smor } Q' . \supset . Q \times P \text{ smor } Q' \times P'$
[$*166\cdot22 . *151\cdot12$]

This proposition enables us to use $Q \times P$ to define the product of the relation-numbers of Q and P, for it shows that the relation-number of $Q \times P$ is determinate when the relation-numbers of Q and P are given. We shall therefore (in Section D of this part) define the product of two relation-numbers ν and μ as the relation-number of $Q \times P$ when $N_0r`Q = \nu$ and $N_0r`P = \mu$.

$*166\cdot24.\ \vdash :. \text{Mult ax} . \supset : R \in \text{Rel}^2 \text{ excl} \cap \text{Nr}`Q . C`R \subset \text{Nr}`P . \supset .$
$\Sigma`R \text{ smor } Q \times P$ [$*165\cdot38 . *164\cdot151 . *166\cdot1$]

This proposition exhibits the connection of addition and multiplication. If we put $\text{Nr}`P = \mu$ and $\text{Nr}`Q = \nu$, then $\Sigma`R$ in the above proposition is the sum of $\nu$ relations of which each is a $\mu$. In virtue of the above proposition, it follows that (if the multiplicative axiom is assumed) $\text{Nr}`\Sigma`R = \nu \times \mu$. In other words, assuming the multiplicative axiom, the sum of ν series (or other relations), each of which has μ terms, has $\nu \times \mu$ terms.

$*166\cdot3.\ \vdash : \exists ! C`(P \times Q) \cap C`(P' \times Q') . \equiv . \exists ! C`P \cap C`P' . \exists ! C`Q \cap C`Q'$
[$*166\cdot12 . *113\cdot19$]

The analogous proposition
$\dot{\exists} ! (P \times Q) \mathbin{\dot{\cap}} (P' \times Q') . \equiv :$
$\dot{\exists} ! (P \mathbin{\dot{\cap}} P') . \exists ! C`Q \cap C`Q' . \lor . \dot{\exists} ! (Q \mathbin{\dot{\cap}} Q') . \exists ! C`P \cap C`P'$
is only true in general if $P \mathrel{\dot{\subset}} J . P' \mathrel{\dot{\subset}} J$

$*166\cdot31.\ \vdash . s`C`(Q \times P) = C`P \uparrow C`Q$ [$*113\cdot115 . *166\cdot12$]

$*166\cdot311.\ \vdash : \dot{\exists} ! Q . \supset . s`D``C`(Q \times P) = C`P : \dot{\exists} ! P . \supset . s`\text{Ǝ}``C`(Q \times P) = C`Q$
[$*113\cdot116 . *166\cdot12 . *33\cdot24$]

$*166\cdot312.\ \vdash . s`D``C`(Q \times P) \subset C`P . s`\text{Ǝ}``C`(Q \times P) \subset C`Q$
[$*113\cdot118 . *166\cdot12$]

The following propositions are lemmas for the associative law ($*166\cdot42$).

$*166\cdot4.\ \vdash :. M \{(P \times Q) \times R\} M' . \equiv : (\exists x, y, z, x', y', z') :$

***166·42.** $\vdash . (P \times Q) \times R \operatorname{smor} P \times (Q \times R)$ [*166·41]

This is the associative law for the kind of multiplication concerned in this number.

***166·421.** $P \times Q \times R = (P \times Q) \times R$ Df

This definition serves merely for the avoidance of brackets.

The two following propositions give the distributive law. In relation-arithmetic, this is in general only true in one of its two forms, *i.e.* we have

$$(Q \dotplus R) \times P = (Q \times P) \dotplus (R \times P),$$

but not $$P \times (Q \dotplus R) = (P \times Q) \dotplus (P \times R).$$

The latter is true for finite series, but not for infinite series or (except in exceptional cases) for relations which are not serial.

***166·44.** $\vdash . \Sigma\text{‘} \times P ; Q = (\Sigma\text{‘}Q) \times P$

Dem.

$$\begin{aligned}
&\vdash . *166{\cdot}1 . *38{\cdot}11 . *150{\cdot}1 . \supset \vdash . \Sigma\text{‘} \times P ; Q = \Sigma\text{‘}\Sigma ; (P \underset{;}{\downarrow}) \dagger ; Q \\
&[*162{\cdot}34{\cdot}35] \quad = \Sigma\text{‘}P \underset{;}{\downarrow} ; \Sigma\text{‘}Q \\
&[*166{\cdot}1] \quad = (\Sigma\text{‘}Q) \times P . \supset \vdash . \text{Prop}
\end{aligned}$$

***166·45.** $\vdash . (Q \dotplus R) \times P = (Q \times P) \dotplus (R \times P)$

Dem.

$$\begin{aligned}
&\vdash . *166{\cdot}1 . \supset \vdash . (Q \times P) \dotplus (R \times P) = \Sigma\text{‘}P \underset{;}{\downarrow} ; Q \dotplus \Sigma\text{‘}P \underset{;}{\downarrow} ; R \\
&[*162{\cdot}31] \quad = \Sigma\text{‘}(P \underset{;}{\downarrow} ; Q \dotplus P \underset{;}{\downarrow} ; R) \\
&[*162{\cdot}36] \quad = \Sigma\text{‘}P \underset{;}{\downarrow} ; (Q \dotplus R) \\
&[*166{\cdot}1] \quad = (Q \dotplus R) \times P . \supset \vdash . \text{Prop}
\end{aligned}$$

The following propositions (*166·46—·472) exhibit the failure of the distributive law in the form $P \times (Q \dotplus R) = (P \times Q) \dotplus (P \times R)$, and give certain results for special cases. They are not referred to except in this number.

SECTION C

THE PRINCIPLE OF FIRST DIFFERENCES, AND THE MULTIPLICATION AND EXPONENTIATION OF RELATIONS

Summary of Section C.

In the present section, we have to consider various forms of a principle which is of the utmost utility in relation-arithmetic. This principle may be called "the principle of first differences." It has been explained and used by Hausdorff in brilliant articles*. The results there obtained by its use give some measure of its importance in relation-arithmetic. It has, however, other uses besides those that are concerned with the multiplication and exponentiation of relation-numbers, as, for example, in the ordering of segments and stretches in a series, or of any other set of classes which are contained in the field of a given relation. In the present section, after the first two numbers, we shall be concerned with its arithmetical uses, but other uses will occur later.

The principle of first differences has various forms which, though analogous, cannot, in the general case, be reduced to one common genus. The simplest of these is the relation P_{cl}, by which the sub-classes of $C‘P$ are ordered. This is defined as follows. If α and β are both contained in $C‘P$, we say that $\alpha P_{\text{cl}} \beta$ if there are terms belonging to α but not to β such that no terms belonging to β and not to α precede them; *i.e.* if, after taking away the terms (if any) which are common to α and β, there are terms left in α which do not come after any of the terms left in β, *i.e.* if $\exists ! \alpha - \beta - \breve{P}‘‘(\beta - \alpha)$. Thus the definition is

$$P_{\text{cl}} = \hat{\alpha}\hat{\beta}\{\alpha, \beta \in \text{Cl}‘C‘P \,.\, \exists ! \alpha - \beta - \breve{P}‘‘(\beta - \alpha)\} \quad \text{Df.}$$

It will be seen that this relation holds if $\beta \subset \alpha \,.\, \beta \neq \alpha$. Thus it holds between any existent member of $\text{Cl}‘C‘P$ and Λ, and between $C‘P$ and any member of $\text{Cl}‘C‘P$ other than $C‘P$ itself. When P is a serial relation (which is the important case for all the relations in this section), P_{cl} is transitive ($P^2_{\text{cl}} \in P_{\text{cl}}$) and asymmetrical ($P_{\text{cl}} \dot{\cap} \breve{P}_{\text{cl}} = \dot{\Lambda}$), but not necessarily *connected*, *i.e.* there may be two members of its field of which neither has the relation P_{cl} to the other. This happens whenever P is not well-ordered; but when P is well-ordered, P_{cl} is connected, and therefore generates a series.

* "Untersuchungen über Ordnungstypen," *Berichte der mathematisch-physischen Klasse der Königlich Sächsischen Gesellschaft der Wissenschaften zu Leipzig*, Feb. 1906 and Feb. 1907. Cf. also his "Grundzüge einer Theorie der geordneten Mengen," *Math. Annalen*, 65 (1908).

To illustrate the order generated by P_{cl} in a simple case, consider a series of three terms, x, y, z. Let us for the moment write $(x \downarrow y \downarrow z)$ for the relation

$$x \downarrow y \cup x \downarrow z \cup y \downarrow z, \quad i.e. \ (x \downarrow y) \rightarrow\!\!\!\!\!+ z,$$

and similarly we will write $(x \downarrow y \downarrow z \downarrow w)$ for $x \downarrow y \downarrow z \rightarrow\!\!\!\!\!+ w$, and so on. Then assuming $x \neq y \,.\, x \neq z \,.\, y \neq z$,

$$(x \downarrow y \downarrow z)_{\text{cl}} = (\iota\text{`}x \cup \iota\text{`}y \cup \iota\text{`}z) \downarrow (\iota\text{`}x \cup \iota\text{`}y) \\ \downarrow (\iota\text{`}x \cup \iota\text{`}z) \downarrow \iota\text{`}x \downarrow (\iota\text{`}y \cup \iota\text{`}z) \downarrow \iota\text{`}y \downarrow \iota\text{`}z \downarrow \Lambda.$$

In this series, a class containing x is always earlier than one not containing x; and of two classes of which both or neither contain x, one containing y is earlier than one not containing y; and of two classes of which both or neither contain x, and both or neither contain y, one containing z is earlier than one not containing z. Thus our relation may be generated as follows: Begin with $(\iota\text{`}z) \downarrow \Lambda$, which is $(z \downarrow z)_{\text{cl}}$. Add before these terms what results from adding $\iota\text{`}y$ to each; then we have $(y \downarrow z)_{\text{cl}}$, which is

$$(\iota\text{`}y \cup \iota\text{`}z) \downarrow \iota\text{`}y \downarrow \iota\text{`}z \downarrow \Lambda.$$

Now add at the beginning what results from adding $\iota\text{`}x$ to each of the above four classes, and we have $(x \downarrow y \downarrow z)_{\text{cl}}$. Thus generally, if $x \sim \epsilon\, C\text{`}P$,

$$(x \leftarrow\!\!\!\!\!+ P)_{\text{cl}} = (\iota\text{`}x \cup)^{;} P_{\text{cl}} \ \ddagger\ P_{\text{cl}}.$$

Thus by adding one term to P, we double the number of terms in P_{cl}.

Again, if P and Q are two relations which have no common terms in their fields, we shall have

$$\alpha P_{\text{cl}} \beta \,.\, \gamma, \delta \,\epsilon\, \text{Cl}\text{`}C\text{`}Q \,.\supset.\, (\alpha \cup \gamma)(P \ddagger Q)_{\text{cl}} (\beta \cup \delta)$$

and $$\alpha \,\epsilon\, \text{Cl}\text{`}C\text{`}P \,.\, \gamma Q_{\text{cl}} \delta \,.\supset.\, (\alpha \cup \gamma)(P \ddagger Q)_{\text{cl}} (\alpha \cup \delta),$$

while conversely

$$\alpha, \beta \,\epsilon\, \text{Cl}\text{`}C\text{`}P \,.\, \gamma, \delta \,\epsilon\, \text{Cl}\text{`}C\text{`}Q \,.\, (\alpha \cup \gamma)(P \ddagger Q)_{\text{cl}} (\beta \cup \delta) \,.\supset:\\ \alpha P_{\text{cl}} \beta \,.\vee.\, \alpha = \beta \,.\, \gamma Q_{\text{cl}} \delta.$$

Hence $$(\alpha \cup \gamma)(P \ddagger Q)_{\text{cl}} (\beta \cup \delta) \,.\equiv.\, (\gamma \downarrow \alpha)(P_{\text{cl}} \times Q_{\text{cl}})(\delta \downarrow \beta) \\ \equiv .\, (\alpha \cup \gamma) \{s^{;} C^{;} (P_{\text{cl}} \times Q_{\text{cl}})\} (\beta \cup \delta),$$

so that $$\text{Nr}\text{`}(P \ddagger Q)_{\text{cl}} = \text{Nr}\text{`}P_{\text{cl}} \times \text{Nr}\text{`}Q_{\text{cl}}.$$

These propositions illustrate the connection of P_{cl} with multiplication.

Besides P_{cl}, we often require (though not in this Part) the relation which is the converse of $(\breve{P})_{\text{cl}}$. This relation we call P_{lc}, so that

$$P_{\text{lc}} = \text{Cnv}\text{`}(\breve{P})_{\text{cl}} \quad \text{Df.}$$

This begins with Λ, and ends with $C\text{`}P$.

Thus we shall have, for example,

$$(x \downarrow y \downarrow z)_{\mathrm{lc}} = \Lambda \downarrow \iota\text{‘}x \downarrow \iota\text{‘}y \downarrow (\iota\text{‘}x \cup \iota\text{‘}y)$$
$$\downarrow \iota\text{‘}z \downarrow (\iota\text{‘}x \cup \iota\text{‘}z) \downarrow (\iota\text{‘}y \cup \iota\text{‘}z) \downarrow (\iota\text{‘}x \cup \iota\text{‘}y \cup \iota\text{‘}z).$$

Here, if we start from $\Lambda \downarrow \iota\text{‘}x$, which is $(x \downarrow x)_{\mathrm{lc}}$, the series grows by adding terms at the end: we add $\iota\text{‘}y$ to each member of $\Lambda \downarrow \iota\text{‘}x$, and put the resulting terms $\iota\text{‘}y$, $\iota\text{‘}x \cup \iota\text{‘}y$ after Λ and $\iota\text{‘}x$; we then add $\iota\text{‘}z$ to each of the four terms we already have, and add the resulting terms at the end; and so we can proceed indefinitely.

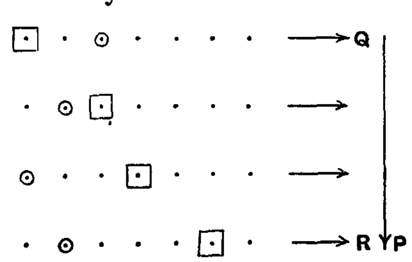
The relation P_{lc} with its field limited arranges the *segments* of P in ascending order of magnitude; if the class of segments is σ, $P_{\mathrm{lc}} \upharpoonright \sigma$ generates what may be called the natural order among the segments (cf. $*212$).

A variant of P_{cl} is afforded by the relation P_{df} ($*171$), which is to hold between two members α, β of $\mathrm{Cl}\text{‘}C\text{‘}P$ when the first term of either which does not belong to both belongs to α, *i.e.* the "first difference" belongs to α. This relation implies P_{cl}, and coincides with it if P is well-ordered; but when P is not well-ordered, P_{cl} may hold between two classes which have no *first* point of difference, *e.g.* (if P is "less than" among rationals) if α consists of rationals between 0 and 1 (both excluded) and β of rationals between 1 and 2 (both excluded). The definition of P_{df} is

$$P_{\mathrm{df}} = \hat{\alpha}\hat{\beta}\,\{\alpha, \beta \in \mathrm{Cl}\text{‘}C\text{‘}P : (\exists z) \,.\, z \in \alpha - \beta \,.\, \overrightarrow{P}\text{‘}z \cap \alpha - \iota\text{‘}z = \overrightarrow{P}\text{‘}z \cap \beta\} \quad \mathrm{Df.}$$

The relation P_{df} has the interesting property that its relation-number is found by raising 2_r to the power $\mathrm{Nr}\text{‘}P$ (cf. $*177$). As the field of P_{df} is $\mathrm{Cl}\text{‘}C\text{‘}P$, this theorem is the ordinal analogue of $\mathrm{Nc}\text{‘}\mathrm{Cl}\text{‘}\alpha = 2^{\mathrm{Nc}\text{‘}\alpha}$ ($*116{\cdot}72$).

A somewhat more complicated form of the relation of first differences arises when we have a series of series. Let us suppose, to begin with, that P is a serial relation whose field consists of mutually exclusive serial relations. Thus in the accompanying figure, each row represents a series, the generating relations of these series being $Q, \ldots R, \ldots$. But the series themselves form a series, which may be regarded as generated by a relation P whose field consists of the relations $Q, \ldots R, \ldots$. (It might be thought more natural to take $C\text{‘}Q$, $C\text{‘}R, \ldots$ as the field of P; but this would lead to confusion in the case when two or more of the series have the same field.) Suppose we now wish to find a relation which will order the multiplicative class of the fields of $Q, R, \ldots$, *i.e.* the class $\mathrm{Prod}\text{‘}C\text{“}C\text{‘}P$. In the case illustrated in the figure, in which P generates a well-ordered series, and all the members of $C\text{‘}P$ are serial, and $P \in \mathrm{Rel}^2\,\mathrm{excl}$, we might use $(\Sigma\text{‘}P)_{\mathrm{cl}}$; this relation, with its field limited to $\mathrm{Prod}\text{‘}C\text{“}C\text{‘}P$, will then give us what we want. This relation will, in the case supposed, put



a selected class μ before another selected class ν if, where they first differ, μ chooses an earlier term than ν. But if the series P is not well-ordered—if it is (say) of the type $\mathrm{Cnv}``\omega$ (cf. $*263$)—there may be no *first* member of the field of P where μ and ν differ. This will happen, for example, if μ consists of all the first terms, and ν of all the second terms. Our ordering relation can be so defined as to put μ before ν in this case also, but if it is so defined, the associative law of multiplication only holds if P is well-ordered. For this reason, we define our ordering relation so that, in such a case, μ comes neither before nor after ν. Again, if P is not a $\mathrm{Rel}^2\,\mathrm{excl}$, a member of a selected class may occur twice, once as the representative of $C`Q$, and once as that of $C`R$, if $C`Q$ and $C`R$ have terms in common. We wish to distinguish these two occurrences. Hence we proceed as follows: If μ and ν are two selected classes of $C``C`P$, let there be one or more members of $C`P$ in which the μ-representative precedes the ν-representative, and which are such that, among all earlier* members of $C`P$, the μ-representative is identical with the ν-representative.

But a further modification is desirable in order to meet the case in which two or more of the members of $C`P$ have the same field. Suppose, for example, we had to deal with a series consisting of all the series that can be formed out of a given set of terms: in this case, we should have to distinguish occurrences of any given term not by the field, but by the generating relation. This requires that we should make an F-selection from $C`P$, not an ϵ-selection from $C``C`P$. Hence we take two members of $F_\Delta`C`P$, say $M$ and $N$, and we arrange them or their domains on the following principle: We put $M$ before $N$ (or $\mathrm{D}`M$ before $\mathrm{D}`N$) if there is a relation $Q$ in the field of $P$ such that the $M$-representative of $Q$, *i.e.* $M`Q$, has the relation Q to the N-representative of Q, and such that, if R is any earlier member of $C`P$, then $M`R$ is identical with $N`R$. That is, M precedes N if

$$(\exists Q):(M`Q)\,Q\,(N`Q):RPQ\,.\,R\neq Q\,.\supset_R.\,M`R=N`R.$$

The relation between M and N so defined has the properties required of an arithmetical product; hence we put

$$\Pi`P=\hat{M}\hat{N}\{M,N\,\epsilon\,F_\Delta`C`P:.\;(\exists Q):(M`Q)\,Q\,(N`Q):RPQ\,.\,R\neq Q\,.\supset_R.\,M`R=N`R\}\quad\mathrm{Df.}$$

This relation is the ordinal analogue of $\epsilon_\Delta`\kappa$. The ordinal analogue of $\mathrm{Prod}`\kappa$ is the corresponding relation of the domains of M and N, *i.e.* $\mathrm{D}{;}\Pi`P$; hence we put

$$\mathrm{Prod}`P=\mathrm{D}{;}\Pi`P\quad\mathrm{Df.}$$

In case P is a $\mathrm{Rel}^2\,\mathrm{excl}$, we have $\mathrm{Nr}`\mathrm{Prod}`P=\mathrm{Nr}`\Pi`P$. But when P is not a $\mathrm{Rel}^2\,\mathrm{excl}$, $\mathrm{Prod}`P$ and $\Pi`P$ are in general not ordinally similar. We can, however, always make a $\mathrm{Rel}^2\,\mathrm{excl}$ by replacing the members x, y, etc. of

* Here Q is said to be *earlier* than R if Q has the relation P to R and is not identical with R.

$C'Q$ (where $Q \epsilon C'P$) by $x \downarrow Q$, $y \downarrow Q$, etc. In this way, if x occurs twice in $C'\Sigma'P$, once as a member of $C'Q$, and once as a member of $C'R$, the two occurrences are made to correspond to $x \downarrow Q$ and $x \downarrow R$ respectively, and thus we get a new relation which *is* a Rel^2 excl.

If every member of $C'P$ has a first term, $B \upharpoonright C'P$ will be the first term of $\Pi'P$, and $B``C'P$ will be the first term of Prod$'P$. If further there is a last member of $C'P$, *i.e.* if $E ! B'\breve{P}$, and if this last member has a second term, the second member of $\Pi'P$ is obtained by taking this second term as the representative of $B'\breve{P}$, and leaving all the other representatives unchanged. In any case, if $B'\breve{P}$ exists, the earliest successors of any member of $\Pi'P$ are those obtained by only varying the representative in $B'\breve{P}$. Thus, if $B'\breve{P}$ exists, those members of $\Pi'P$ which have a given set of representatives in all members of $D'P$ form a consecutive stretch of the series, and this stretch is like $B'\breve{P}$. If $B'\breve{P}$ has an immediate predecessor, the stretches obtained by varying only the representative in this predecessor are again consecutive, and form a series like the said predecessor; and so on. This makes it plain why $\Pi'P$ has the properties of a product.

As in the case of cardinals, the definition of exponentiation is derived from that of multiplication. We put

$$P \exp Q = \text{Prod}'P \underset{\bullet}{\downarrow} {}^{;}Q \quad \text{Df.}$$

We put also $\qquad P^Q = \dot{s}{}^{;}(P \exp Q) \quad \text{Df.}$

This is an important relation, which deserves consideration apart from the fact that it is useful in connection with exponentiation. It will be found that

$$P^Q = \hat{M}\hat{N}\{M, N \epsilon (C'P \uparrow C'Q)_\Delta{}'C'Q :. \\ (\exists y) : y \epsilon C'Q \,.\, (M'y) \, P \, (N'y) : xQy \,.\, x \neq y \,.\, \supset_x \,.\, M'x = N'x\}.$$

This is a form of the principle of first differences which is appropriate when *two* relations are concerned, instead of only one as in P_{cl}. The principle, in this case, is as follows: Let M, N be any two one-many relations which relate part (or the whole) of $C'P$ to the whole of $C'Q$. That is, each of the two relations assigns a representative in $C'P$ to every term of $C'Q$, but different terms of $C'Q$ may have the same representative. Then in travelling along the series Q, there is to be, sooner or later, a term y whose M-representative is earlier than its N-representative, and terms which come earlier than y in Q are all to have their M-representatives identical with their N-representatives.

The relation P^Q may be subjected to various restrictions which give important results. This subject has been treated by Hausdorff. For

example, if $P = x \downarrow y$ (where $x \neq y$), and Q is of the ordinal type which Cantor calls ω, *i.e.* the type of progressions (generated by transitive relations), then if z is any member of $C`Q$, $M`z$ is always either x or y. If we impose the condition that $M`z$ is to be $x$ except for a finite number of values of $z$, the resulting series is of the type of the rationals in order of magnitude, *i.e.* the type called $\eta$. If we impose the condition that there are to be an infinite number of values of $z$ for which $M`z = y$, the resulting series is a continuum, *i.e.* it is of the ordinal type called θ; in this case, the contained "rational" series consists of those M's for which there are only a finite number of z's having $M`z = x$. If we impose no limitation, P^Q is of the type presented by the real numbers when decimals ending in 9 recurring are counted separately from the terminating decimals having the same value.

We may generalize P^Q, instead of restricting it. To begin with, we may allow our M and N to have only part of $C`Q$ for their converse domain, and remove the assumption that there is a *first* member of $C`Q$ for which $M`y$ and $N`y$ differ; this leads to the relation

$$\hat{M}\hat{N}\{M, N \in (1 \rightarrow \mathrm{Cls}) \cap \mathrm{Rl}`(C`P \uparrow C`Q) :.$$
$$(\exists y) : (M`y)\, P\, (N`y) : xQy \,.\, x \in \text{Ɑ}`N \,.\, \supset_x .\, (M`x)(P \cup I)(N`x)\}.$$

Further, we may drop the restriction to one-many relations. It will be observed that if $(M`y)\, P\, (N`y)$, we have $y\, (\breve{M} \,|\, P \,|\, N)\, y$. Thus we may consider the relation

$$MN [\hat{M}, \hat{N} \in \mathrm{Rl}`(C`P \uparrow C`Q) :.$$
$$(\exists y) : y\, (\breve{M} \,|\, P \,|\, N)\, y : xQy \,.\, \supset_x .\, x \{\breve{M} \,|\, (P \cup I) \,|\, N\}\, x].$$

This relation has for its field all relations contained in $C`P \uparrow C`Q$. We may, if we like, drop even this restriction, and consider

$$\hat{M}\hat{N}\, [(\exists y) : y \in C`Q \,.\, y\, (\breve{M} \,|\, P \,|\, N)\, y : xQy \,.\, \supset_x .\, x \{\breve{M} \,|\, (P \cup I \upharpoonright C`P) \,|\, N\}\, x].$$

This represents the most general form of the principle of first differences as applied to a couple of relations P and Q. In ordinal arithmetic, however, P^Q is sufficiently general for the uses we wish to make of it.

The formal laws, as far as they are true, can be proved without excessive difficulty. We have

$$\vdash : P \neq Q \,.\, \supset .\, \mathrm{Nr}`\Pi`(P \downarrow Q) = \mathrm{Nr}`(P \times Q),$$

which connects the two kinds of multiplication;

$$\vdash : P \text{ smor smor } Q \,.\, \supset .\, \mathrm{Nr}`\Pi`P = \mathrm{Nr}`\Pi`Q,$$
$$\vdash : P \in \mathrm{Rel}^2 \text{ excl} \,.\, P \subset J \,.\, \supset .\, \mathrm{Nr}`\Pi`\Pi;P = \mathrm{Nr}`\Pi`\Sigma`P,$$

which is one form of the associative law, of which another form is

$$\vdash : P \neq Q \,.\, \supset .\, \mathrm{Nr}`(\Pi`P \times \Pi`Q) = \mathrm{Nr}`\Pi`(P \mathbin{\updownarrow} Q).$$

Also

$$\vdash : P, \Sigma\text{‘}P \in \mathrm{Rel}^2\,\mathrm{excl} \,.\, P \subset J \,.\, \supset .\, \mathrm{Nr}\text{‘}\mathrm{Prod}\text{‘}\mathrm{Prod};P = \mathrm{Nr}\text{‘}\mathrm{Prod}\text{‘}\Sigma\text{‘}P = \mathrm{Nr}\text{‘}\Pi\text{‘}\Sigma\text{‘}P,$$

which is the associative law for "Prod." We have

$$\vdash : C\text{‘}Q \cap C\text{‘}R = \Lambda \,.\, \supset .\, \mathrm{Nr}\text{‘}(P^Q \times P^R) = \mathrm{Nr}\text{‘}P^{Q \ddagger R},$$

$$\vdash .\, \mathrm{Nr}\text{‘}(P^Q)^R = \mathrm{Nr}\text{‘}(P^{R \times Q}).$$

But we do not have in general

$$\mathrm{Nr}\text{‘}(P^R \times Q^R) = \mathrm{Nr}\text{‘}(P \times Q)^R,$$

which obviously would require the commutative law for multiplication, and therefore does not hold in general in spite of the fact that its cardinal analogue does always hold.

As regards the connection with cardinals, we have

$$\vdash : P \in \mathrm{Rel}^2\,\mathrm{excl} \,.\, \supset .\, C\text{‘}\mathrm{Prod}\text{‘}P = \mathrm{Prod}\text{‘}C\text{“}C\text{‘}P,$$

$$\vdash : \dot{\exists}\,!\,Q \,.\, \supset .\, C\text{‘}(P \exp Q) = (C\text{‘}P) \exp (C\text{‘}Q),$$

and we have already had

$$\vdash .\, C\text{‘}(P \times Q) = C\text{‘}P \times C\text{‘}Q.$$

Moreover the correlators by which similarity is established in cardinals generally suffice to establish likeness in the analogous cases in relation-arithmetic. Thus we have

$$\vdash : S \in P \,\overline{\mathrm{smor}}\, Q \,.\, \supset .\, S_\epsilon \restriction \mathrm{Cl}\text{‘}C\text{‘}Q \in P_{\mathrm{cl}} \,\overline{\mathrm{smor}}\, Q_{\mathrm{cl}},$$

$$\vdash : P, Q \in \mathrm{Rel}^2\,\mathrm{excl} \,.\, S \restriction C\text{‘}\Sigma\text{‘}Q \in P \,\overline{\mathrm{smor}}\,\overline{\mathrm{smor}}\, Q \,.\, \supset . \\ S_\epsilon \restriction C\text{‘}\mathrm{Prod}\text{‘}Q \in (\mathrm{Prod}\text{‘}P) \,\overline{\mathrm{smor}}\, (\mathrm{Prod}\text{‘}Q),$$

$$\vdash : S \restriction C\text{‘}P' \in P \,\overline{\mathrm{smor}}\, P' \,.\, T \restriction C\text{‘}Q' \in Q \,\overline{\mathrm{smor}}\, Q' \,.\, \supset . \\ (S \parallel \breve{T}) \restriction C\text{‘}(P' \exp Q') \in (P \exp Q) \,\overline{\mathrm{smor}}\, (P' \exp Q'),$$

which are all closely analogous to propositions which were proved in cardinals.

The applications of the propositions of this section are almost wholly to series, and it is convenient to imagine our relations to be serial. But the hypothesis that they are serial is not necessary to the truth of any of the propositions of the present section, and it is a remarkable fact that so many of the formal laws of ordinal arithmetic hold for relations in general.

It should be observed that $\Pi\text{‘}P$ is not always a series when P is a series and all the relations in the field of P are series. A series (cf. *204) is a relation P which is (1) contained in diversity, (2) transitive, (3) connected, *i.e.* such that every term of the field of P has the relation P or the relation $\breve{P}$ to every other term of the field. It is the third condition which may fail for $\Pi\text{‘}P$, and which in fact does fail whenever P is not well-ordered. Thus suppose, for the sake of simplicity, that P is of the type $\mathrm{Cnv}\text{“}\omega$, which we will call a *regression*, *i.e.* the converse of a progression (cf. *263); and suppose that the field of P consists entirely of couples. Take a selection M

which chooses the first term of every odd couple, and the second term of every even couple; and take another selection N which chooses the second term of every odd couple, and the first term of every even couple. Neither of these two selections has the relation $\Pi‘P$ to the other, for whatever term Q of $C‘P$ we choose, if M is the selection which chooses the first term of Q, there is an earlier term of $C‘P$ (namely the immediate predecessor of Q) in which N chooses the first term while M chooses the second. Hence there is no such Q as is required for $M(\Pi‘P)N$; and a similar argument holds against $N(\Pi‘P)M$. In such a case, $\Pi‘P$ generates a number of different series, and by suitable restrictions of the field, one of these series can be extracted. Exactly similar remarks apply to P^Q.

$*170$. ON THE RELATION OF FIRST DIFFERENCES AMONG THE SUB-CLASSES OF A GIVEN CLASS

Summary of $*170$.

The definition to be given in this number of the relation of first differences among the sub-classes of a given class is by no means the only one possible, in fact a different definition will be considered in $*171$. In the present number, the definition we choose is this: α is said to precede β according to this definition when α has at least one member which neither belongs to β nor follows any term belonging to β and not to α (α and β being both sub-classes of $C\text{‘}P$). In other words, if we consider the two classes $\alpha - \beta$ and $\beta - \alpha$, there are members of $\alpha - \beta$ which are not preceded by any members of $\beta - \alpha$. Pictorially, we may conceive the relation as follows (P being supposed serial): α and β each pick out terms from $C\text{‘}P$, and these terms have an order conferred by P; we suppose that the earlier terms selected by α and β are perhaps the same, but sooner or later, if $\alpha \neq \beta$, we must come to terms which belong to one but not to the other. We assume that the earliest terms of this sort belong to α, not to β; in this case, α has to β the relation P_{cl}. That is, where α and β begin to differ, it is terms of α that we come to, not terms of β. We do not assume that there is a *first* term which belongs to α and not to β, since this would introduce undesirable restrictions in case P is not well-ordered.

A few of the propositions of the present number will be used in the next number, which deals with a slightly different form of the relation of first differences, but with this exception the propositions of this number will not be referred to again until we come to series. Their chief use occurs in the section on compact series, rational series, and continuous series (Part V, Section F), especially in $*274$ and $*276$, which respectively establish the existence of rational series (assuming the axiom of infinity) and the fact that the cardinal number of terms in a continuous series is the same as the number of classes contained in the field of a progression, *i.e.* $2^{\aleph_0}$. The definitions and a few of the simpler propositions are also used in connection with the series of segments of a series, since, as explained above, the segments of a series P are arranged in the series generated by P_{1c}.

The propositions of this number which will be used in dealing with series are the following:

$*170{\cdot}1$. $\vdash : \alpha P_{cl} \beta . \equiv . \alpha, \beta \in \text{Cl}\text{‘}C\text{‘}P . \exists ! \alpha - \beta - \breve{P}\text{‘‘}(\beta - \alpha)$

$*170{\cdot}101$. $\vdash . P_{1c} = \text{Cnv}\text{‘}(\breve{P})_{cl}$

$*170{\cdot}102$. $\vdash : \alpha P_{1c} \beta . \equiv . \alpha, \beta \in \text{Cl}\text{‘}C\text{‘}P . \exists ! \beta - \alpha - P\text{‘‘}(\alpha - \beta)$

(These propositions merely embody the definitions.)

$*170\cdot11.\ \vdash :. \alpha P_{cl} \beta . \equiv : \alpha, \beta \in \mathrm{Cl}'C'P : (\exists y) . y \in \alpha - \beta . \overrightarrow{P}'y \cap \beta \subset \alpha$

This form is often more convenient than $*170\cdot1$.

$*170\cdot16.\ \vdash : \alpha \subset C'P . \beta \subset \alpha . \beta \neq \alpha . \supset . \alpha P_{cl} \beta$

I.e. every sub-class of $C'P$ has the relation P_{cl} to every proper part of itself.

$*170\cdot17.\ \vdash . P_{cl} \Subset J . P_{lc} \Subset J$

$*170\cdot2.\ \vdash :. \alpha, \beta \in \mathrm{Cl}'C'P : (\exists y) . y \in \alpha - \beta . \overrightarrow{P}'y \cap \alpha = \overrightarrow{P}'y \cap \beta : \supset . \alpha P_{cl} \beta$

This proposition deals with the case where there is a definite first term y which belongs to α and not to β, and whose predecessors all belong to both or neither.

$$*170\cdot23.\ \vdash :. \alpha \subset C'P . y \in \alpha - \beta - \breve{P}``(\beta - \alpha) . \supset : y \min_P (\alpha - \beta) . \equiv . \overrightarrow{P}'y \cap \alpha = \overrightarrow{P}'y \cap \beta$$

This proposition is useful in case P is well-ordered, since then $\alpha - \beta$ must have a minimum if it exists (α and β being supposed sub-classes of $C'P$).

$*170\cdot31.\ \vdash : \beta \subset C'P . \beta \neq C'P . \equiv . (C'P) P_{cl} \beta$

This follows from $*170\cdot16$, as does the following proposition:

$*170\cdot32.\ \vdash : \alpha \subset C'P . \exists ! \alpha . \equiv . \alpha P_{cl} \Lambda$

$*170\cdot35.\ \vdash . \dot{\Lambda}_{cl} = \dot{\Lambda}$

$*170\cdot38.\ \vdash : \dot{\exists} ! P . \supset . B'P_{cl} = C'P . B'\mathrm{Cnv}'P_{cl} = \Lambda$

$*170\cdot6.\ \vdash : \Lambda P_{lc} \beta . \equiv . \beta \subset C'P . \exists ! \beta$

Besides the above, the following propositions should be noted:

$*170\cdot36.\ \vdash . \mathrm{D}'P_{cl} = \mathrm{Cl\ ex}'C'P . \mathrm{Q}'P_{cl} = \mathrm{Cl}'C'P - \iota'C'P$

$*170\cdot37.\ \vdash : \dot{\exists} ! P . \supset . C'P_{cl} = \mathrm{Cl}'C'P$

$*170\cdot44.\ \vdash : P \operatorname{smor} Q . \supset . P_{cl} \operatorname{smor} Q_{cl}$

$*170\cdot64.\ \vdash : x \sim \in C'P . \supset . (x \leftarrow\!\!\!+ P)_{cl} = (\iota'x \cup)^{;} P_{cl} \ \hat{+}\ P_{cl}$

This proposition shows that every term added to P doubles the number of terms in P_{cl}; hence it is not surprising that P_{cl} (when P is well-ordered) has a power of 2_r for its relation-number (cf. $*177$).

$*170\cdot67.\ \vdash : \dot{\exists} ! P . \dot{\exists} ! Q . C'P \cap C'Q = \Lambda . \supset . (P \ \hat{+}\ Q)_{cl} = s^{;}C^{;}(P_{cl} \times Q_{cl})$
whence

$*170\cdot69.\ \vdash : \dot{\exists} ! P . \dot{\exists} ! Q . C'P \cap C'Q = \Lambda . \supset . (P \ \hat{+}\ Q)_{cl} \operatorname{smor} (P_{cl} \times Q_{cl})$

$*170\cdot01.\ P_{cl} = \hat{\alpha}\hat{\beta} \{\alpha, \beta \in \mathrm{Cl}'C'P . \exists ! \alpha - \beta - \breve{P}``(\beta - \alpha)\} \quad \mathrm{Df}$

$*170\cdot02.\ P_{lc} = \mathrm{Cnv}'(\breve{P})_{cl} \quad \mathrm{Df}$

$*170\cdot 1$. $\vdash : \alpha P_{cl} \beta . \equiv . \alpha, \beta \in \mathrm{Cl}`C`P . \exists ! \alpha - \beta - \breve{P}``(\beta - \alpha)$ [$(*170\cdot 01)$]

$*170\cdot 101$. $\vdash . P_{1c} = \mathrm{Cnv}`(\breve{P})_{cl}$ [$(*170\cdot 02)$]

$*170\cdot 102$. $\vdash : \alpha P_{1c} \beta . \equiv . \alpha, \beta \in \mathrm{Cl}`C`P . \exists ! \beta - \alpha - P``(\alpha - \beta)$ [$*170\cdot 1\cdot 101$]

Thus $\alpha P_{1c} \beta$ means, roughly speaking, that $\beta - \alpha$ goes on longer than $\alpha - \beta$, just as $\alpha P_{cl} \beta$ means that $\alpha - \beta$ begins sooner. Thus if P is the relation of earlier and later in time, and α and β are the times when A and B respectively are out of bed, "$\alpha P_{cl} \beta$" will mean that A gets up earlier than B, and "$\alpha P_{1c} \beta$" will mean that B goes to bed later than A.

In order that P_{cl} should be serial, we need further that it should be transitive and connected. P_{cl} is transitive if P is transitive and connected. But P_{cl} may still not be connected: there may be many distinct families in its field, though all of them must begin with $C`P$ and end with Λ. For example, if P is a regression, the class which takes every odd member does not have either of the relations $P_{\mathrm{cl}}, \breve{P}_{\mathrm{cl}}$ to the class which takes every even member. In order that P_{cl} should be serial, we require that P should be not only serial, but well-ordered, *i.e.* that every existent sub-class of $C`P$ should have a first term. When P is serial but not well-ordered, P_{cl} will, however, generate various series contained in it by imposing suitable limitations on the field.

*171. THE PRINCIPLE OF FIRST DIFFERENCES (*continued*)

Summary of *171.

In this number, we shall consider a more restricted form of the principle of first differences, which is applicable when there is a definite first member of one class not belonging to the other class. In this case, if z is the first differing member, the part of α which precedes z is to be the same as the part of β which precedes z. If z belongs to α and not to β, we put α before β; in the converse case, we put β before α. In case zPz, z itself is not to be counted among its own predecessors; thus the predecessors of z are to be $\overrightarrow{P}\text{‘}z - \iota\text{‘}z$. Hence the relation in question will hold between two sub-classes (α and β) of $C\text{‘}P$ when there is a z such that

$$z \epsilon \alpha - \beta \,.\, \overrightarrow{P}\text{‘}z - \iota\text{‘}z \cap \alpha = \overrightarrow{P}\text{‘}z - \iota\text{‘}z \cap \beta,$$

or, what comes to the same thing (owing to $z \sim\epsilon \beta$),

$$z \epsilon \alpha - \beta \,.\, \overrightarrow{P}\text{‘}z \cap \alpha - \iota\text{‘}z = \overrightarrow{P}\text{‘}z \cap \beta.$$

This relation between α and β we denote by "P_{df}," where "df" stands for "difference."

Thus our definition is

$$P_{\text{df}} = \hat{\alpha}\hat{\beta}\,\{\alpha, \beta \epsilon \text{Cl}\text{‘}C\text{‘}P : (\exists z) \,.\, z \epsilon \alpha - \beta \,.\, \overrightarrow{P}\text{‘}z \cap \alpha - \iota\text{‘}z = \overrightarrow{P}\text{‘}z \cap \beta\} \quad \text{Df.}$$

On the analogy of P_{lc}, we put also

$$P_{\text{fd}} = \text{Cnv}\text{‘}(\breve{P})_{\text{df}}.$$

When P is well-ordered, P_{df} and P_{fd} coincide respectively with P_{cl} and P_{lc}. Their properties are closely analogous to those of P_{cl} and P_{lc}. Thus *e.g.* the following propositions remain true when P_{df} is substituted for P_{cl}:

*170·17·35·36·37·38·44·5·51·52·64·67·68·69.

The only new propositions to be noted in this number are

***171·2.** $\vdash : P \in J \,.\, \supset .$

$$P_{\text{df}} = \hat{\alpha}\hat{\beta}\,\{\alpha, \beta \epsilon \text{Cl}\text{‘}C\text{‘}P : (\exists z) \,.\, z \epsilon \alpha - \beta \,.\, \overrightarrow{P}\text{‘}z \cap \alpha = \overrightarrow{P}\text{‘}z \cap \beta\}$$

***171·21.** $\vdash . P_{\text{df}} \in P_{\text{cl}}$

and the following formulae suggesting an inductive identification of P_{cl} and P_{df} in cases to which such induction is applicable:

***171·7.** $\vdash : P_{\text{df}} = P_{\text{cl}} \,.\, x \sim\epsilon C\text{‘}P \,.\, \supset .\, (x \leftarrow\!\!\!+ P)_{\text{df}} = (x \leftarrow\!\!\!+ P)_{\text{cl}}$

***171·71.** $\vdash : C\text{‘}P \cap C\text{‘}Q = \Lambda \,.\, P_{\text{df}} = P_{\text{cl}} \,.\, Q_{\text{df}} = Q_{\text{cl}} \,.\, \supset .\, (P \updownarrow Q)_{\text{df}} = (P \updownarrow Q)_{\text{cl}}$

These propositions are however superseded (at a later stage) by the proof that P_{cl} and P_{df} coincide if P is well-ordered (*251·37).

The chief property of P_{df} is that its relation-number is 2_r to the power $\text{Nr}\text{‘}P$. This will be proved in *177 and *186·4.

***171·01.** $P_{df} = \hat{\alpha}\hat{\beta}\{\alpha, \beta \epsilon \text{Cl}`C`P : (\exists z) . z \epsilon \alpha - \beta . \overrightarrow{P}`z \cap \alpha - \iota`z = \overrightarrow{P}`z \cap \beta\}$ Df

$*172$. THE PRODUCT OF THE RELATIONS OF A FIELD

Summary of $*172$.

In this number we have to consider the form of product which is applicable to any relation of relations, whether mutually exclusive or not. If our relation were a $\mathrm{Rel}^2\,\mathrm{excl}$, we could take $C``C`P$, and order selected classes from $C``C`P$ by first differences. This would give us a relation whose field would be $\mathrm{Prod}`C``C`P$. But if any two fields overlap, this method fails. We might substitute $\epsilon_\Delta`C``C`P$ for $\mathrm{Prod}`C``C`P$, and order the members of $\epsilon_\Delta`C``C`P$ by first differences; but this method will not give what we want if two or more members of $C`P$ have the same field. In order to avoid any confusion due to repetition, we must, if $Q \,\epsilon\, C`P$ and $x \,\epsilon\, C`Q$, consider x in connection with Q, not merely with $C`Q$. That is, the relations in the field of the product of $P$ must be such as concern themselves with the ordered couple $x \downarrow Q$, not merely with $x$. The simplest way of effecting this is to consider $F_\Delta`C`P$. A member of $F_\Delta`C`P$, say $M$, is a relation which picks out a representative of $Q$ from the field of every $Q$ which is a member of $C`P$; that is, whenever $Q \,\epsilon\, C`P$, $M`Q \,\epsilon\, C`Q$. Since we have $M`Q$, not $M`C`Q$, two relations may have the same field and yet we can distinguish the occurrence of a given term as the representative of the one from its occurrence as the representative of the other. Thus no degree of overlapping will cause confusion.

The relations which compose $F_\Delta`C`P$ are to be ordered by first differences, but in order to distinguish different occurrences of a given term, we must give a slightly different form to the principle of first differences from that employed in $*170$ or $*171$. The new form of the principle is as follows: Consider two relations M and N which are members of $F_\Delta`C`P$. Let Q be a member of $C`P$ in which $M$ chooses a representative which precedes that of $N$, *i.e.* in which $(M`Q)\,Q\,(N`Q)$; and let all earlier relations than $Q$, *i.e.* all relations $R$ such that $RPQ$ and $R \neq Q$, have $M`R = N`R$. Then we say that $M$ precedes $N$. This principle may also be stated as follows: We may divide the members of $C`P$ into four classes, not in general mutually exclusive, namely:

(1) those in which $(M`Q)\,Q\,(N`Q)$, *i.e.* in which the M-representative precedes the N-representative;

(2) those in which $(N`Q)\,Q\,(M`Q)$,

(3) those in which $M`Q = N`Q$,

(4) those in which no one of the above three relations of $M`Q$ and $N`Q$ occurs.

Then we shall say that M precedes N if there is a member of class (1) whose predecessors all belong to class (3).

In case all the members of $C'P$ are serial, the fourth of the above classes is null, and the other three are mutually exclusive. If, further, P is well-ordered, any two different members of $F_\Delta{}'C'P$ must be such that one precedes the other in the above-defined order. Thus in this case the product of a series of series is a series (cf. $*251$).

The definition of the product $\Pi'P$ is

$$\Pi'P = \hat{M}\hat{N}\{M, N \in F_\Delta{}'C'P :. (\exists Q) : (M'Q)\, Q\, (N'Q) : RPQ \,.\, R \neq Q \,.\, \supset_R \,.\, M'R = N'R\} \quad \text{Df.}$$

Owing to the complication of this definition, the proofs of propositions of the present number are apt to be long.

Various other definitions might be adopted for $\Pi'P$, but we have found the above definition on the whole the best.

We might, for example, drop the condition $R \neq Q$ in the definition; we could then write our definition in the simpler form:

$$\Pi'P = \hat{M}\hat{N}\{M, N \in F_\Delta{}'C'P : (\exists Q) \,.\, (M'Q)\, Q\, (N'Q) \,.\, M \upharpoonright \overrightarrow{P}'Q = N \upharpoonright \overrightarrow{P}'Q\},$$

which, with our definition, is only available when $P \subset J$. But if we adopt this simplification, we no longer have

$$\Pi'(P \downarrow P) = P \underset{\centerdot\centerdot}{\downarrow} P \quad (*172{\cdot}2),$$

which is a very useful proposition, required in the proofs of $*183{\cdot}13$, $*185{\cdot}21$ and other important propositions.

On the other hand, we might frame our definition on the analogy of P_{cl} rather than, as above, on the analogy of P_{df}. The definition would then be:

$$\Pi'P = \hat{M}\hat{N}\{M, N \in F_\Delta{}'C'P :. (\exists Q) : (M'Q)\, Q\, (N'Q) : RPQ \,.\, \supset_R \,.\, (M'R)\,(R \cup I)\,(N'R)\}.$$

This definition does not assume that there is a *first* relation Q for which the M-representative precedes the N-representative. Thus it might be thought that it would give better results in cases where P is not well-ordered. But in fact this is not the case. If P is not well-ordered, it may happen that every Q for which $(M'Q)\, Q\, (N'Q)$ is preceded by one for which $(N'Q)\, Q\, (M'Q)$, *and vice versa*; in this case, we shall have neither $M\,(\Pi'P)\,N$ nor $N\,(\Pi'P)\,M$. Thus our suggested new definition does not secure that $\Pi'P$ shall be a series whenever P and all the members of $C'P$ are series, and therefore has no substantial advantage over the simpler definition which we have adopted, and has the disadvantage of greater complication.

In the present number, we first prove that $\Pi'\dot{\Lambda} = \dot{\Lambda}$ ($*172{\cdot}13$) and that $\dot{\Lambda} \in C'P \,.\, \supset \,.\, \Pi'P = \dot{\Lambda}$ ($*172{\cdot}14$), so that a product is null if any one of its factors is null. We then proceed to propositions about $C'\Pi'P$, $\overrightarrow{B}'\Pi'P$, etc. We have

$$*172{\cdot}162. \vdash : \dot{\exists} ! P \,.\, \supset \,.\, \overrightarrow{B}'\Pi'P = B_\Delta{}'C'P \,.\, \overrightarrow{B}'\text{Cnv}'\Pi'P = B_\Delta{}'\text{Cnv}''C'P$$

*172·17. $\vdash : \dot{\exists} ! P . \supset . C`\Pi`P = F_\Delta`C`P$

Hence we derive propositions as to the existence of $\Pi`P$. We have

*172·181. $\vdash :. \text{Mult ax} . \supset : \Lambda \sim\epsilon C`P . \dot{\exists} ! P . \equiv . \dot{\exists} ! \Pi`P$

Thus assuming the multiplicative axiom, a product which has factors none of which are null is not null.

We then consider $\Pi`(P \downarrow P)$, and $\Pi`(P \downarrow Q)$ where $P \neq Q$. We have

*172·2. $\vdash . \Pi`(P \downarrow P) = P \underset{\cdot\cdot}{\downarrow} P$

which is a useful proposition, and

*172·23. $\vdash : P \neq Q . \supset . \Pi`(P \downarrow Q) \operatorname{smor} P \times Q$

which connects the two definitions of multiplication, showing that they lead to equivalent results for any finite number of factors, *i.e.* whenever the definition of *166 is applicable.

We next consider $\Pi`(P \nrightarrow Z)$ and $\Pi`(P \ddagger Q)$, proving

*172·32. $\vdash : Z \sim\epsilon C`P . \supset . \Pi`(P \nrightarrow Z) \operatorname{smor} \Pi`P \times Z$

with a similar proposition for $Z \nleftarrow P$ (*172·321), and

*172·35. $\vdash : \dot{\exists} ! P . \dot{\exists} ! Q . C`P \cap C`Q = \Lambda . \supset . \Pi`(P \ddagger Q) \operatorname{smor} \Pi`P \times \Pi`Q$

which is a form of the associative law using both kinds of multiplication. The kind which uses only Π will be proved in *174.

We have next the proof (with its immediate consequences) that if P and Q have double likeness, $\Pi`P \operatorname{smor} \Pi`Q$. We prove

*172·43. $\vdash : T \upharpoonright C`\Sigma`Q \,\epsilon\, P \,\overline{\operatorname{smor}}\, \overline{\operatorname{smor}}\, Q . \supset .$

$$(T \| \operatorname{Cnv}`T\dagger) \upharpoonright C`\Pi`Q \,\epsilon\, (\Pi`P) \,\overline{\operatorname{smor}}\, (\Pi`Q)$$

This proposition should be compared with *114·51, which is its cardinal analogue. It will be seen that the correlator only differs by the substitution of $T\dagger$ for T_ϵ. From *172·43 we obtain

*172·44. $\vdash : P \operatorname{smor} \operatorname{smor} Q . \supset . \Pi`P \operatorname{smor} \Pi`Q$

whence

*172·45. $\vdash :. \text{Mult ax} . \supset : P, Q \,\epsilon\, \text{Rel}^2 \text{excl} . \exists ! P \,\overline{\operatorname{smor}}\, Q \cap \text{Rl}`\text{smor} . \supset .$

$$\Pi`P \operatorname{smor} \Pi`Q$$

Other propositions about $\Pi`P$ will be given in *174.

$$\Pi‘P \,\text{smor}\, \Pi‘Q$$

$[*164\cdot44 \,.\, *172\cdot44]$

The following proposition shows that if two relations have the same field, and if the parts of them that are contained in diversity are the same, they have the same product. Thus *e.g.* $\Pi‘P_{\text{po}} = \Pi‘P_*$, in virtue of $*91\cdot541$.

$*172\cdot5$. $\vdash : C‘P = C‘Q \,.\, P \dot{\cap} J = Q \dot{\cap} J \,.\supset.\, \Pi‘P = \Pi‘Q$

Dem.

$\vdash \,.\, *50\cdot11 \,.\supset \vdash :.\, \text{Hp} \,.\supset : RPS \,.\, R \neq S \,.\equiv.\, RQS \,.\, R \neq S \quad (1)$

$\vdash \,.\, (1) \,.\, *172\cdot11 \,.\supset \vdash .\, \text{Prop}$

The following proposition is used in $*182\cdot42$.

$*172\cdot51$. $\vdash .\, \Pi‘P = \Pi‘(P \cup I \upharpoonright C‘P) \quad [*172\cdot5]$

$*172\cdot52$. $\vdash :.\, Q \in Ɑ‘P \,.\supset_Q .\, (\exists R) \,.\, RPQ \,.\, R \neq Q : \supset .\, \Pi‘P = \Pi‘(P \dot{\cap} J)$

Dem.

$\vdash \,.\, *50\cdot11 \,. \quad \supset \vdash : \text{Hp} \,.\supset.\, Ɑ‘P \subset Ɑ‘(P \dot{\cap} J) \quad (1)$

$\vdash \,.\, *33\cdot14 \,.\, *93\cdot101 \,.\, \text{Transp} \,.\supset \vdash : QPQ \,.\supset.\, Q \sim\in \overrightarrow{B}‘P :$

$[\text{Transp}.*33\cdot13] \quad \supset \vdash : Q \in \overrightarrow{B}‘P \,.\supset.\, (\exists R) \,.\, QPR \,.\, R \neq Q \,.$

$[*50\cdot11] \quad \supset .\, Q \in C‘(P \dot{\cap} J) \quad (2)$

$\vdash \,.\, (1) \,.\, (2) \,.\, *93\cdot103 \,. \quad \supset \vdash : \text{Hp} \,.\supset.\, C‘P \subset C‘(P \dot{\cap} J) \,.$

$[*33\cdot265] \quad \supset .\, C‘P = C‘(P \dot{\cap} J) \quad (3)$

$\vdash \,.\, (3) \,.\, *172\cdot5 \,.\supset \vdash .\, \text{Prop}$

Thus we shall always have $\Pi‘P = \Pi‘(P \dot{\cap} J)$ unless there are members of $Ɑ‘P$ which have no referent except themselves.

$*173$. THE PRODUCT OF THE RELATIONS OF A FIELD (*continued*)

Summary of $*173$.

In this number, we shall consider the relation between the domains of relations related by $\Pi‘P$, *i.e.* we shall consider $\mathrm{D};\Pi‘P$. This relation bears to $\Pi‘P$ a relation analogous to that which $\mathrm{Prod}‘\kappa$ bears to $\epsilon_\Delta‘\kappa$. We shall denote it by "$\mathrm{Prod}‘P$." When $P \in \mathrm{Rel}^2\,\mathrm{excl}$, $\mathrm{Prod}‘P$ is like $\Pi‘P$, and is often more convenient than $\Pi‘P$. When $P \in \mathrm{Rel}^2\,\mathrm{excl}$, $\mathrm{Prod}‘P$ arranges the multiplicative class of $C‘‘C‘P$ by first differences, taking first differences to mean that the earliest member Q of $C‘P$ for which $\mu \cap C‘Q \neq \nu \cap C‘Q$ has the μ-member earlier than the ν-member in the Q-series.

The properties of $\mathrm{Prod}‘P$ all result immediately from those of $\Pi‘P$, and offer no difficulty of any kind. The most important of them are:

$*173{\cdot}14$. $\vdash : \dot{\exists}\,!\,P\,.\,C \upharpoonright C‘P \in 1 \to 1\,.\,\supset .\,C‘\mathrm{Prod}‘P = \mathrm{Prod}‘C‘‘C‘P$

I.e. if P is not null, and no two members of $C‘P$ have the same field, then the field of $\mathrm{Prod}‘P$ is the product of the fields of $C‘P$. Observe that $C \upharpoonright C‘P \in 1 \to 1$ if $P \in \mathrm{Rel}^2\,\mathrm{excl}$.

The above proposition is used in proving the associative law for "Prod" (*174·401).

*174. THE ASSOCIATIVE LAW OF RELATIONAL MULTIPLICATION

Summary of *174.

In the present number, we have to prove the associative law for Π and for Prod, *i.e.* we have to prove (with a suitable hypothesis)

$$\Pi\text{‘}\Pi\,;P \text{ smor } \Pi\text{‘}\Sigma\text{‘}P$$

and $$\text{Prod‘Prod}\,;P \text{ smor Prod‘}\Sigma\text{‘}P.$$

The first of these requires $P \epsilon \text{Rel}^2\text{excl}$ and either $P \mathrel{\mathsf{G}} J$ or

$$QPQ \,.\supset_Q .\, C\text{‘}Q \,\epsilon\, 0 \cup 1\,;$$

the second requires not only this, but also $\Sigma\text{‘}P \,\epsilon\, \text{Rel}^2\text{excl}$. When both P and $\Sigma\text{‘}P$ are relations of mutually exclusive relations, we call P an *arithmetical* relation, which we denote by "Rel^3arithm." Arithmetical relations serve exactly analogous purposes to those served by arithmetical classes in cardinal arithmetic.

The proof of the associative law for Π consists in showing that, under a suitable hypothesis, $\dot{s}\,|\,\text{D}$ (with its converse domain limited) is a correlator of $\Pi\text{‘}\Sigma\text{‘}P$ and $\Pi\text{‘}\Pi\,;P$ (*174·221·23). To prove this, we first prove

***174·17.** $\vdash : P \epsilon \text{Rel}^2\text{excl} \,.\supset .\, \dot{s}\text{“D“}C\text{‘}\Pi\text{‘}\Pi\,;P = C\text{‘}\Pi\text{‘}\Sigma\text{‘}P$

and

***174·19.** $\vdash : P \epsilon \text{Rel}^2\text{excl} \,.\supset .\, (\dot{s}\,|\,\text{D}) \upharpoonright C\text{‘}\Pi\text{‘}\Pi\,;P \,\epsilon\, 1 \to 1$

This gives what we may call the cardinal part of the proof, *i.e.* it shows that $(\dot{s}\,|\,\text{D}) \upharpoonright C\text{‘}\Pi\text{‘}\Pi\,;P$ is a cardinal correlator of the fields of $\Pi\text{‘}\Sigma\text{‘}P$ and $\Pi\text{‘}\Pi\,;P$. We then prove that if M and N belong to the field of $\Pi\text{‘}\Pi\,;P$, they have the relation $\Pi\text{‘}\Pi\,;P$ when the relational sums of their domains have the relation $\Pi\text{‘}\Sigma\text{‘}P$. Here, in addition to the hypothesis $P \epsilon \text{Rel}^2\text{excl}$, we require that if any relation Q has the relation P to itself, then $C\text{‘}Q$ is not to have more than one term. Thus we have

***174·215.** $\vdash :. P \epsilon \text{Rel}^2\text{excl} : QPQ \,.\supset_Q .\, C\text{‘}Q \,\epsilon\, 0 \cup 1 : \supset :$
$$M\,(\Pi\text{‘}\Pi\,;P)\,N \,.\equiv .\, M, N \,\epsilon\, F_\Delta\text{‘}\Pi\text{“}C\text{‘}P \,.\, (\dot{s}\text{‘D‘}M)\,(\Pi\text{‘}\Sigma\text{‘}P)\,(\dot{s}\text{‘D‘}N)$$

The hypothesis $QPQ \,.\supset_Q .\, C\text{‘}Q \,\epsilon\, 0 \cup 1$ is verified if $P \mathrel{\mathsf{G}} J$ (*174·216); thus for most purposes it is more convenient to substitute the simpler hypothesis $P \mathrel{\mathsf{G}} J$ for $QPQ \,.\supset_Q .\, C\text{‘}Q \,\epsilon\, 0 \cup 1$. We shall, however, have occasion to use the hypothesis $QPQ \,.\supset_Q .\, C\text{‘}Q \,\epsilon\, 0 \cup 1$ in *182·42·43·431, where our P is a relation whose field consists entirely of relations of the form $Q \downarrow Q$, whose fields are always unit classes, so that our P satisfies the above hypothesis even if P is not contained in J.

The proof of $*174{\cdot}215$ (above) is effected by first proving

$*174{\cdot}2.$ $\vdash : P \in \text{Rel}^2\,\text{excl} . Q \in C'P . M \in C'\Pi'\Pi;P . \supset . M'\Pi'Q = (\dot{s}'\text{D}'M) \upharpoonright C'Q$

From $*174{\cdot}17{\cdot}19{\cdot}215$ we deduce

$*174{\cdot}221.$ $\vdash :. P \in \text{Rel}^2\,\text{excl} : QPQ . \supset_Q . C'Q \in 0 \cup 1 : \supset .$
$\Pi'\Sigma'P = \dot{s};\text{D};\Pi'\Pi;P . (\dot{s}|\text{D}) \upharpoonright C'\Pi'\Pi;P \in (\Pi'\Sigma'P)\,\overline{\text{smor}}\,(\Pi'\Pi;P)$

whence we obtain the more convenient proposition

$*174{\cdot}23.$ $\vdash : P \in \text{Rel}^2\,\text{excl} . P \subset J . \supset .$
$\Pi'\Sigma'P = \dot{s};\text{D};\Pi'\Pi;P . (\dot{s}|\text{D}) \upharpoonright C'\Pi'\Pi;P \in (\Pi'\Sigma'P)\,\overline{\text{smor}}\,(\Pi'\Pi;P)$

Thus if the hypothesis of $*174{\cdot}221$ or of $*174{\cdot}23$ holds, the associative law holds for Π ($*174{\cdot}241{\cdot}25$).

To prove the associative law for Prod, *i.e.*

$$P \in \text{Rel}^3\,\text{arithm} . P \subset J . \supset . \text{Prod}'\Sigma'P \text{ smor Prod}'\text{Prod};P,$$

we observe that, since $\Pi'\Sigma'P = \dot{s};\text{D};\Pi'\Pi;P$ ($*174{\cdot}23$)
$= \dot{s};\text{Prod}'\Pi;P$, by the definition of Prod,
we have ($*174{\cdot}41$) $\text{Prod}'\Sigma'P = \text{D};\dot{s};\text{Prod}'\Pi;P$
$= s;\text{D}_\epsilon;\text{Prod}'\Pi;P$, by $*41{\cdot}33$,
$= s;\text{Prod}'\text{D}\dagger;\Pi;P$, by $*173{\cdot}33$,
$= s;\text{Prod}'\text{Prod};P$, by the definition of Prod.

Also $s \upharpoonright C'\text{Prod}'\text{Prod};P \in 1 \to 1$, by $*115{\cdot}46$. Hence the associative law follows ($*174{\cdot}43$). It will be observed that in this case the correlator is simply s with its converse domain limited ($*174{\cdot}42$).

As in the case of Π, "$P \subset J$" is a stronger hypothesis than we really need: what we need is $QPQ . \supset_Q . C'Q \in 0 \cup 1$.

$*174{\cdot}01.$ $\text{Rel}^3\,\text{arithm} = \hat{P}(P, \Sigma'P \in \text{Rel}^2\,\text{excl})$ Df

$*174{\cdot}12.$ $\vdash : C \upharpoonright C'P \in 1 \to 1 . \supset . \Pi;P \in \text{Rel}^2\,\text{excl}$

This proposition gives the associative law for Π. It remains to prove the associative law for Prod.

The following propositions are concerned with various properties of "arithmetical" relations, down to $*174\cdot4$, where the proof of the associative law for Prod begins.

$*174\cdot3.\quad \vdash : P \epsilon \text{Rel}^3 \text{arithm} . \equiv . P, \Sigma\text{‘}P \epsilon \text{Rel}^2 \text{excl} \qquad [(*174\cdot01)]$

$*174\cdot31.\quad \vdash :. P \epsilon \text{Rel}^3 \text{arithm} . \equiv : Q, Q' \epsilon C\text{‘}P . Q \neq Q' . \supset_{Q,Q'} . C\text{‘}Q \cap C\text{‘}Q' = \Lambda :$
$R, R' \epsilon C\text{‘}\Sigma\text{‘}P . R \neq R' . \supset_{R,R'} . C\text{‘}R \cap C\text{‘}R' = \Lambda \quad [*174\cdot3 . *163\cdot1]$

$*174\cdot311.\quad \vdash :. P \epsilon \text{Rel}^3 \text{arithm} . \equiv : Q, Q' \epsilon C\text{‘}P . \exists ! C\text{‘}Q \cap C\text{‘}Q' . \supset_{Q,Q'} . Q = Q' :$
$R, R' \epsilon C\text{‘}\Sigma\text{‘}P . \exists ! C\text{‘}R \cap C\text{‘}R' . \supset_{R,R'} . R = R' \quad [*174\cdot3 . *163\cdot11]$

$*176$. EXPONENTIATION

Summary of $*176$.

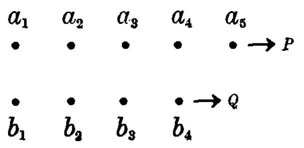
The definition of exponentiation is framed on the analogy of the definition in cardinals, *i.e.* we put

$$P \exp Q = \text{Prod}`P \mathbin{\dot{\downarrow}} {}^{\prime\prime}Q \quad \text{Df.}$$

We put also, what is often a more convenient form,

$$P^Q = \dot{s}{}^{\prime\prime}(P \exp Q) \quad \text{Df.}$$

The relation P^Q has for its field (unless $Q = \dot{\Lambda}$) the class of Cantor's "Belegungen," *i.e.* the class $(C`P \uparrow C`Q)_\Delta`C`Q$. It arranges these by a form of the principle of first differences, namely as follows: Suppose M and N are two members of $(C`P \uparrow C`Q)_\Delta`C`Q$, and suppose there is in $C`Q$ a term $y$ for which the $M$-representative $(M`y)$ precedes the N-representative $(N`y)$, *i.e.* for which $(M`y) \, P \, (N`y)$, and suppose further that all terms in $C`Q$ which are earlier than y, *i.e.* for which $zQy \,.\, z \neq y$, have their M-representative and their N-representative identical; in this case we say that M has to N the relation P^Q. This may be stated as follows, provided we assume that P and Q are series: Let M and N be two one-valued functions whose possible arguments are all the members of $C`Q$, while their values are some or all of the members of $C`P$. Then we say that M has to N the relation P^Q if the first argument for which the two functions do not have the same value gives an earlier value to M than to N. Thus for example let P be the series a_1, a_2, a_3, a_4, a_5, and let Q be the series b_1, b_2, b_3, b_4. Then M and N are to be such that $M`b$ or $N`b$ is defined when, and only when, b is b_1 or b_2 or b_3 or b_4, and the value of $M`b$ or $N`b$ is a_1 or a_2 or a_3 or a_4 or a_5. Then if $M`b_1 = a_1$ and $N`b_1 \neq a_1$, M precedes N; if $M`b_1 = N`b_1 = a_1$, and $M`b_2 = a_1 \,.\, N`b_2 \neq a_1$, M precedes N; and so on. Thus in this case the first term of the series generated by P^Q is the one for which $M`b = a_1$ when $b$ has any of the values $b_1, b_2, b_3, b_4$. Thus the first term of the series is $\iota`a_1 \uparrow C`Q$, *i.e.* $\iota`B`P \uparrow C`Q$. The next term will be



$$\iota`a_1 \uparrow (\iota`b_1 \cup \iota`b_2 \cup \iota`b_3) \cup \iota`a_2 \uparrow \iota`b_4,$$

i.e. $$\iota`B`P \uparrow \text{D}`Q \cup 2_P \downarrow B`\breve{Q}.$$

The next is $$\iota`B`P \uparrow \text{D}`Q \cup 3_P \downarrow B`\breve{Q},$$

and so on. This makes it evident that our series has the structure required of a series which is to represent the Qth power of P.

The two relations $P \exp Q$ and P^Q are ordinally similar, since $\dot{s}$ is one-one when its field is limited to $C`(P \exp Q)$. This follows from $*116 \cdot 131$, together with

$$\exists ! \, Q \,.\, \supset \,.\, C`(P \exp Q) = (C`P) \exp (C`Q).$$

If S is a correlator of P and P', and T is a correlator of Q and Q', then $(S \| \breve{T})_\epsilon$ and $(S \| \breve{T})$, with their converse domains limited, are respectively correlators of $(P \exp Q)$ with $(P' \exp Q')$ and of P^Q with $P'^{Q'}$. This shows that the relation-number of $(P \exp Q)$ depends only upon those of P and Q, which is of course essential if $(P \exp Q)$ is to afford a definition of exponentiation.

If the multiplicative axiom is assumed, then if R is a relation which is like Q, and whose field consists of relations which are like P, and $R \in \mathrm{Rel}^2 \,\mathrm{excl}$, the product of R is like $(P \exp Q)$. That is, if we put $\mu = \mathrm{Nr}\text{‘}P \,.\, \nu = \mathrm{Nr}\text{‘}Q$, so that R consists of ν terms each of which has μ terms, the product of R has μ^ν terms. This gives the connection of multiplication with exponentiation.

There are two formal laws of exponentiation which hold for relation-numbers, namely

$$P^Q \times P^R \,\mathrm{smor}\, P^{Q \dotplus R}$$

and

$$(P^Q)^R \,\mathrm{smor}\, P^{R \times Q}.$$

They both need a hypothesis: the first needs

$$\dot{\exists} \,!\, Q \,.\, \dot{\exists} \,!\, R \,.\, C\text{‘}Q \cap C\text{‘}R = \Lambda,$$

while the second needs $\qquad R \in J$

because it is proved by means of the associative law (*174·43).

The first of the above formal laws can be generalized, by putting $\Sigma\text{‘}S$ in place of $Q \dotplus R$, and taking the product of the various powers

$$P \exp Q,\; P \exp Q', \ldots,$$

where $Q, Q', \ldots \in C\text{‘}S$, and the products are taken in the order determined by S. The resulting generalization is

$$S \in \mathrm{Rel}^2 \,\mathrm{excl} \,.\, S \in J \,.\, \supset \,.\, \{\mathrm{Prod}\text{‘}(P \exp)^{;}S\} \,\mathrm{smor}\, \{P \exp (\Sigma\text{‘}S)\}.$$

The proof of this proposition results immediately from *174·43 and *162·35.

The proof of the second of the formal laws is more difficult. We observe, to begin with, that

$$P \exp (R \times Q) = \mathrm{Prod}\text{‘}P \underset{\cdot\cdot}{\downarrow}{}^{;}\Sigma\text{‘}Q \underset{\cdot\cdot}{\downarrow}{}^{;}R.$$

Assuming suitable hypotheses, this, by *162·35,

$$= \mathrm{Prod}\text{‘}\Sigma\text{‘}(P \underset{\cdot\cdot}{\downarrow})\dagger^{;}Q \underset{\cdot\cdot}{\downarrow}{}^{;}R,$$

which is like $\qquad \mathrm{Prod}\text{‘}\mathrm{Prod}^{;}(P \underset{\cdot\cdot}{\downarrow})\dagger^{;}Q \underset{\cdot\cdot}{\downarrow}{}^{;}R$, by *174·43.

But $\qquad (P \exp Q) \exp R = \mathrm{Prod}\text{‘}\{\mathrm{Prod}\text{‘}P \underset{\cdot\cdot}{\downarrow}{}^{;}Q\} \underset{\cdot\cdot}{\downarrow}{}^{;}R.$

Thus our result will follow if we can prove

$$\{\mathrm{Prod}^{;}(P \underset{\cdot\cdot}{\downarrow})\dagger^{;}Q \underset{\cdot\cdot}{\downarrow}{}^{;}R\} \,\mathrm{smor\,smor}\, \{(\mathrm{Prod}\text{‘}P \underset{\cdot\cdot}{\downarrow}{}^{;}Q) \underset{\cdot\cdot}{\downarrow}{}^{;}R\}.$$

Now one member of the field of $\mathrm{Prod}^{;}(P \underset{\cdot\cdot}{\downarrow})\dagger^{;}Q \underset{\cdot\cdot}{\downarrow}{}^{;}R$ will be

$$\mathrm{Prod}\text{‘}P \underset{\cdot\cdot}{\downarrow}{}^{;}Q \underset{\cdot\cdot}{\downarrow} z, \text{ where } z \in C\text{‘}R.$$

This is like Prod$`P \underset{\cdot,}{\downarrow} {}^{\flat}Q$, because $Q \underset{\cdot,}{\downarrow} z$ smor $Q$. Hence Prod$^{\flat}(P \underset{\cdot,}{\downarrow})\dagger^{\flat} Q \underset{\cdot,}{\downarrow} {}^{\flat}R$ is a series of terms each of which is like Prod$`P \underset{\cdot,}{\downarrow} {}^{\flat}Q$, and the whole series of such terms is like R. If we assumed the multiplicative axiom, this would suffice to prove the result. But it is possible to obtain our result without assuming the multiplicative axiom.

For this purpose, we proceed as follows. The correlator of

$$\text{Prod}`P \underset{\cdot,}{\downarrow} {}^{\flat}Q \underset{\cdot,}{\downarrow} z \text{ and } \text{Prod}`P \underset{\cdot,}{\downarrow} {}^{\flat}Q$$

is $\{|(\text{Cnv}`\downarrow z)\}_\epsilon$, by $*165\cdot361$ and $*172\cdot3$. Call this $M`z$. Then

$$M \epsilon 1 \to 1 : z \epsilon C`R \,.\supset_z .\, (M`z) \epsilon (\text{Prod}`P \underset{\cdot,}{\downarrow} {}^{\flat}Q \underset{\cdot,}{\downarrow} z) \,\overline{\text{smor}}\, (\text{Prod}`P \underset{\cdot,}{\downarrow} {}^{\flat}Q) :$$
$$z, w \epsilon C`R \,.\, \exists ! \,\text{D}`M`z \cap \text{D}`M`w \,.\supset_{z,w} .\, z = w.$$

This, by the help of two or three lemmas, suffices to prove that

$$\{\text{Prod}^{\flat}(P \underset{\cdot,}{\downarrow})\dagger^{\flat} Q \underset{\cdot,}{\downarrow} {}^{\flat}R\} \text{ smor smor } \{(\text{Prod}`P \underset{\cdot,}{\downarrow} {}^{\flat}Q) \underset{\cdot,}{\downarrow} {}^{\flat}R\},$$

whence the result follows.

The principal propositions of the present number are the following:

$*176\cdot1.$ $\vdash . P \exp Q = \text{Prod}`P \underset{\cdot,}{\downarrow} {}^{\flat}Q = \text{D}^{\flat}\Pi`P \underset{\cdot,}{\downarrow} {}^{\flat}Q$

$*176\cdot11.$ $\vdash . P^Q = \dot{s}^{\flat}(P \exp Q) = \dot{s}^{\flat}\text{Prod}`P \underset{\cdot,}{\downarrow} {}^{\flat} Q = \dot{s}^{\flat}\text{D}^{\flat}\Pi`P \underset{\cdot,}{\downarrow} {}^{\flat} Q$

These propositions merely embody the definitions.

$*176\cdot14.$ $\vdash : \dot{\exists} ! Q \,.\supset.\, C`(P \exp Q) = (C`P) \exp (C`Q) \,.\, C`P^Q = (C`P \uparrow C`Q)_\Delta`C`Q$

$*176\cdot151.$ $\vdash :. P = \dot{\Lambda} \,.\vee.\, Q = \dot{\Lambda} : \equiv . P \exp Q = \dot{\Lambda} . \equiv . P^Q = \dot{\Lambda}$

It will be observed that in relation-arithmetic, $\mu^0 = 0$, whereas in cardinal arithmetic $\mu^0 = 1$. The difference is due to the fact that there is no ordinal number 1 (cf. $*153$).

$*176\cdot181.$ $\vdash . P^Q \text{ smor } (P \exp Q)$

$*176\cdot182.$ $\vdash . (P \exp Q) \text{ smor } (\Pi`P \underset{\cdot,}{\downarrow} {}^{\flat} Q)$

$*176\cdot19.$ $\vdash :: S (P^Q) T . \equiv :. S, T \epsilon (C`P \uparrow C`Q)_\Delta`C`Q :.$
$$(\exists y) : y \epsilon C`Q \,.\, (S`y) P (T`y) : y'Qy \,.\, y' \neq y \,.\supset_{y'} .\, S`y' = T`y'$$

$*176\cdot2.$ $\vdash : U \upharpoonright C`R \epsilon P \,\overline{\text{smor}}\, R \,.\, W \upharpoonright C`S \epsilon Q \,\overline{\text{smor}}\, S \,.\supset .$
$$(U \| \breve{W})_\epsilon \upharpoonright C`(R \exp S) \epsilon (P \exp Q) \,\overline{\text{smor}}\, (R \exp S)$$

$*176\cdot21.$ With the same hypothesis, $(U \| \breve{W}) \upharpoonright C`(R^S)$ correlates P^Q and R^S

$*176\cdot22.$ $\vdash : P \text{ smor } R \,.\, Q \text{ smor } S \,.\supset .\, (P \exp Q) \text{ smor } (R \exp S) \,.\, P^Q \text{ smor } R^S$

$*176\cdot24.$ $\vdash :. \text{Mult ax} \,.\supset :$
$$R \epsilon \text{Rel}^2 \text{ excl} \cap \text{Nr}`Q \,.\, C`R \subset \text{Nr}`P \,.\supset .\, \Pi`R \text{ smor } (P \exp Q)$$

This proposition connects multiplication and exponentiation.

$*176\cdot31.$ $\vdash : \dot{\exists} ! Q \,.\supset .\, \overrightarrow{B}`(P \exp Q) = (\overrightarrow{B}`P) \exp (C`Q)$

***176·311·32·321.** Similar propositions for $\overrightarrow{B}$'Cnv'$(P \exp Q)$, $\overrightarrow{B}$'(P^Q), $\overrightarrow{B}$'(Cnv'P^Q)

The above proposition is used in $*176{\cdot}19$. It has the merit of giving a direct formula for $P \exp Q$, instead of one which proceeds by way of $\Pi`P \downarrow ; Q$.

$*176{\cdot}13$. $\vdash : \dot{\exists} ! (P \exp Q) . \equiv . \dot{\exists} ! P^Q . \equiv . \dot{\exists} ! \Pi`P \downarrow ; Q$ $[*150{\cdot}25 . *176{\cdot}1{\cdot}11]$

$*176{\cdot}131$. $\vdash : Q = \dot{\Lambda} . \supset . P \exp Q = \dot{\Lambda} . P^Q = \dot{\Lambda}$ $[*165{\cdot}241 . *173{\cdot}2 . *150{\cdot}42]$

Owing to this proposition, propositions stating analogies between ordinal and cardinal powers mostly require the hypothesis $\dot{\exists} ! Q$ or its equivalent, because an ordinal power whose index is zero is itself zero, whereas a cardinal power whose index is zero is 1.

$*176{\cdot}132$. $\vdash : P = \dot{\Lambda} . \dot{\exists} ! Q . \supset . P \exp Q = \dot{\Lambda} . P^Q = \dot{\Lambda}$

$*177$. PROPOSITIONS CONNECTING P_{df} WITH PRODUCTS AND POWERS

Summary of $*177$.

The principal proposition on this subject is

$*177\cdot13$. $\vdash : x \neq y . \supset . P_{df} \operatorname{smor} \{(x \downarrow y)^P\}$

which is the analogue of $*116\cdot72$, or rather leads to the analogue of $*116\cdot72$ as soon as powers of relation-numbers have been defined; for then it becomes

$$P_{df} \in 2_r^{\mathrm{Nr}`P}.$$

Another proposition is an extension of $*171\cdot69$, namely

$*177\cdot22$. $\vdash : P \in \mathrm{Rel}^2 \operatorname{excl} . P \subset J . \supset . \mathrm{Prod}`\mathrm{df};P \operatorname{smor} (\Sigma`P)_{df}$

where we put $\mathrm{df}`Q = Q_{df}$.

The remaining propositions of this number are lemmas for the above two.

$*177\cdot13$ shows, for example, that all classes of finite integers can be arranged in a series of which the relation-number is 2_r^{ω}, where ω is the relation-number of the series of finite integers. 2_r^{ω} is not the relation-number of the continuum, but is closely allied to it.

$*177\cdot1$. $\vdash : x \neq y . T = \hat{\mu}\hat{R}[R \in \{(\iota`x \cup \iota`y) \uparrow \alpha\}_\Delta`\alpha . \mu = \overleftarrow{R}`x] . \supset .$

$$T \in (\mathrm{Cl}`\alpha) \overline{\mathrm{sm}} \{(\iota`x \cup \iota`y) \uparrow \alpha\}_\Delta`\alpha \quad [*116\cdot712\cdot713\cdot715]$$

In the propositions of $*116$ referred to, Λ and V appear in place of x and y, but no property of Λ and V is used in the proof except $\Lambda \neq \mathrm{V}$.

$*177\cdot11$. $\vdash : \mathrm{Hp}*177\cdot1 . \alpha = C`P . \supset . T;(x \downarrow y)^P = P_{df}$

Dem.

$\vdash . *176\cdot19 . \supset$

$\vdash ::. \mathrm{Hp} . \supset :: \mu \{T;(x \downarrow y)^P\} \nu . \equiv :. (\exists R, S) : R, S \in \{(\iota`x \cup \iota`y) \uparrow C`P\}_\Delta`C`P :$

$wPz . w \neq z . \supset_w : w \in \mu . \equiv . w \in \nu :.$

$[*171\cdot11] \equiv :. \mu (P_{df}) \nu ::. \supset \vdash . \mathrm{Prop}$

***177·12.** $\vdash : \mathrm{Hp}*177\cdot11 . \supset . T \epsilon P_{\mathrm{df}} \overline{\mathrm{smor}} \{(x \downarrow y)^P\}$ [*177·1·11 . *151·191]

***177·13.** $\vdash : x \neq y . \supset . P_{\mathrm{df}} \mathrm{smor} \{(x \downarrow y)^P\}$ [*177·12]

***177·2.** $\mathrm{df}‘Q = Q_{\mathrm{df}}$ Dft [*177]

***177·21.** $\vdash : P \epsilon \mathrm{Rel}^2 \mathrm{excl} . P \subset J . \supset . s \restriction C‘\mathrm{Prod}‘\mathrm{df};P \epsilon (\Sigma‘P)_{\mathrm{df}} \overline{\mathrm{smor}} (\mathrm{Prod}‘\mathrm{df};P)$

The proof proceeds as the proof of *174·24 proceeds. If $Q \epsilon C‘P$, we shall have, if $M \epsilon F_\Delta‘\mathrm{df}“C‘P$,

$$M‘Q_{\mathrm{df}} = (s‘\mathrm{D}‘M) \cap C‘Q.$$

Hence we easily obtain

$$M(\Pi‘\mathrm{df};P)N . \equiv . M, N \epsilon F_\Delta‘\mathrm{df}“C‘P . (s‘\mathrm{D}‘M)(\Sigma‘P)_{\mathrm{df}}(s‘\mathrm{D}‘N),$$

whence

$$\mu(\mathrm{Prod}‘\mathrm{df};P)\nu . \equiv . \mu, \nu \epsilon \mathrm{Prod}‘\mathrm{Cl}“C“C‘P . (s‘\mu)(\Sigma‘P)_{\mathrm{df}}(s‘\nu),$$

whence the result follows easily.

***177·22.** $\vdash : P \epsilon \mathrm{Rel}^2 \mathrm{excl} . P \subset J . \supset . \mathrm{Prod}‘\mathrm{df};P \,\mathrm{smor}\, (\Sigma‘P)_{\mathrm{df}}$ [*177·21]

SECTION D

ARITHMETIC OF RELATION-NUMBERS

Summary of Section D.

In the present section, we shall be concerned with the arithmetical operations on relation-numbers. Their purely logical properties have been dealt with in Section A; in the present section, it is their arithmetical properties that are to be established. These properties result immediately from the arithmetical properties of relations which have been established in Sections B and C. The subjects treated of in the present section are analogous to those treated of in Section B of Part III, with the exception of such as have already had their analogues discussed in Sections B and C of Part IV. The analogy is sufficiently close to render it often unnecessary to give proofs, since these are often step by step analogous to the proofs of corresponding propositions in Part III, Section B.

The two chief requisites in defining the arithmetical operations with relation-numbers are (1) to take due account of types, (2) to construct what may be called *separated* relations, *i.e.* relations of mutually exclusive relations derived from and ordinally similar to given relations. Each of these points calls for some preliminary explanations.

The sum of two relation-numbers μ, ν will be denoted by "$\mu \dotplus \nu$," in order to distinguish this kind of addition from $\mu + \nu$ (the arithmetical addition of classes) and $\mu +_c \nu$ (the addition of cardinals). In defining $\mu \dotplus \nu$, we have to take account of the following considerations.

Suppose P and Q are two relations which are of the same type, and have mutually exclusive fields. Then obviously we shall want to frame our definition of the sum of two relation-numbers in such a way that the sum of $\mathrm{Nr}\text{‘}P$ and $\mathrm{Nr}\text{‘}Q$ shall be $\mathrm{Nr}\text{‘}(P \uparrow\!\!\!\!+ Q)$. But if P and Q are not of the same type, $P \uparrow\!\!\!\!+ Q$ is meaningless; and if $C\text{‘}P$ and $C\text{‘}Q$ overlap, $P \uparrow\!\!\!\!+ Q$ may be too small to have as its relation-number the sum of the relation-numbers of P and Q. Both these difficulties can be met by observing that, if $\mathrm{Nr}\text{‘}P = \mathrm{Nr}\text{‘}R$ and $\mathrm{Nr}\text{‘}Q = \mathrm{Nr}\text{‘}S$, we must make such definitions as to have

$$\mathrm{Nr}\text{‘}P \dotplus \mathrm{Nr}\text{‘}Q = \mathrm{Nr}\text{‘}R \dotplus \mathrm{Nr}\text{‘}S.$$

Hence, in defining the sum of the relation-numbers of P and Q, we may replace P and Q by any two relations R and S which are respectively like P and Q. Therefore what we require for our definition is to find two relations R and S which (1) are respectively like P and Q, (2) are of the

same type, (3) have mutually exclusive fields. All these three requisites are satisfied if we put

$$R = \downarrow (\Lambda \cap C\text{‘}Q) \,;\, \iota \,;\, P \,.\, S = (\Lambda \cap C\text{‘}P) \downarrow \,;\, \iota \,;\, Q.$$

We then define $P + Q$ as meaning $R \,\ddagger\, S$, and we define the sum of the relation-numbers of P and Q as the relation-number of $P + Q$. This procedure is exactly analogous to that of *110; in fact, we have

$$C\text{‘}(P + Q) = C\text{‘}P + C\text{‘}Q.$$

In defining the sum of the relation-numbers of a field, we do not have to consider types, because the members of a field are necessarily all of the same type. But we do have to consider the question of overlapping. If a term x occurs both in $C\text{‘}Q$ and in $C\text{‘}R$, where $Q, R \in C\text{‘}P$, we want a method of counting x twice over in forming the arithmetical sum. Thus $\mathrm{Nr}\text{‘}\Sigma\text{‘}P$ cannot be taken as the sum of the relation-numbers of members of $C\text{‘}P$, unless $P \in \mathrm{Rel}^2\,\mathrm{excl}$. Suppose, for instance, we have three series

$$(a, b, c), \quad (b, c, a), \quad (c, a, b).$$

These each have three terms; and we want the sum of their relation-numbers to be the relation-number of a series of nine terms. But if we put

$Q = a \downarrow b \downarrow c$ (where $a \downarrow b \downarrow c$ is written for $a \downarrow b \cup a \downarrow c \cup b \downarrow c$),
$R = b \downarrow c \downarrow a$,
$S = c \downarrow a \downarrow b$,

and if we further put

$P = Q \downarrow R \downarrow S$,

so that P places the above three series in the above order, we have

$$\Sigma\text{‘}P = (\iota\text{‘}a \cup \iota\text{‘}b \cup \iota\text{‘}c) \uparrow (\iota\text{‘}a \cup \iota\text{‘}b \cup \iota\text{‘}c),$$

which is not a series, and does not have the relation-number which we require as the sum of the relation-numbers of Q, R, S.

What is wanted is a method of distinguishing the various occurrences of a and b and c. For this reason, when a occurs as a member of the field of Q, we replace it by $a \downarrow Q$; when as a member of the field of R, by $a \downarrow R$; and when as a member of the field of S, by $a \downarrow S$. Thus the series (a, b, c) is replaced by $(a \downarrow Q, b \downarrow Q, c \downarrow Q)$; (b, c, a) is replaced by $(b \downarrow R, c \downarrow R, a \downarrow R)$; and (c, a, b) is replaced by $(c \downarrow S, a \downarrow S, b \downarrow S)$. The sum of these three series then has the relation-number which is required as the sum of the relation-numbers of Q, R, S.

The above process is symbolized as follows. The generating relation of the series $(a \downarrow Q, b \downarrow Q, c \downarrow Q)$ is $\downarrow Q \,;\, Q$; thus the three relations whose sum is to be taken are $\downarrow Q \,;\, Q$, $\downarrow R \,;\, R$, $\downarrow S \,;\, S$, *i.e.* using the notation of *182, according to which we put $\overset{\frown}{\text{♀}}\text{‘}x = x \,\text{♀}\, x$, our three relations are $\overset{\frown}{\underset{;}{\downarrow}}\text{‘}Q$, $\overset{\frown}{\underset{;}{\downarrow}}\text{‘}R$, $\overset{\frown}{\underset{;}{\downarrow}}\text{‘}S$.

But the generating relation of the series $(\overset{\frown}{\underset{\text{;}}{\downarrow}}\text{‘}Q,\ \overset{\frown}{\underset{\text{;}}{\downarrow}}\text{‘}R,\ \overset{\frown}{\underset{\text{;}}{\downarrow}}\text{‘}S)$ is $\overset{\frown}{\underset{\text{;}}{\downarrow}}\,;P$, since $P = (Q \downarrow R \downarrow S)$. Thus $\overset{\frown}{\underset{\text{;}}{\downarrow}}\,;P$ is the relation required for defining the sum of the relation-numbers of members of the field of P; *i.e.* we put

$$\Sigma \mathrm{Nr}\text{‘}P = \mathrm{Nr}\text{‘}\Sigma\text{‘}\overset{\frown}{\underset{\text{;}}{\downarrow}}\,;P \quad \text{Df.}$$

We will call $\overset{\frown}{\underset{\text{;}}{\downarrow}}\,;P$ the *separated* relation corresponding to P. $\overset{\frown}{\underset{\text{;}}{\downarrow}}\,;P$ is constructed, as above, by replacing every member x of $C\text{‘}Q$, where $Q \in C\text{‘}R$, by $x \downarrow Q$; so that if x belongs both to $C\text{‘}Q$ and to $C\text{‘}R$, it is duplicated by being transformed once into $x \downarrow Q$, and once again into $x \downarrow R$.

For the treatment of products, we do not require $\overset{\frown}{\underset{\text{;}}{\downarrow}}\,;P$, because $\Pi\text{‘}P$ has been so defined as to effect the requisite separation. We might, however, by the use of $\overset{\frown}{\underset{\text{;}}{\downarrow}}\,;P$, have dispensed with $\Pi\text{‘}P$ as a fundamental notion, and contented ourselves with $\mathrm{Prod}\text{‘}P$; for we have

$$\Pi\text{‘}P = \dot{s}\,;\mathrm{Prod}\text{‘}\overset{\frown}{\underset{\text{;}}{\downarrow}}\,;P.$$

Thus we might have taken Prod as the fundamental notion, and defined Π by means of it.

The addition of unity to a relation-number has to be treated separately from the addition of two relation-numbers, for the same reasons which necessitate the treatment of $P \mathbin{+\!\!\rightarrow} x$ and $x \mathbin{\leftarrow\!\!+} P$ separately from $P \mathbin{\overset{\uparrow}{+}} Q$. There is no ordinal number 1, but we can define the *addition* of one to a relation-number. If $\mathrm{Nr}\text{‘}P = \mu$ and $x \sim\in C\text{‘}P$, we must have

$$\mathrm{Nr}\text{‘}(P \mathbin{+\!\!\rightarrow} x) = \mu \dot{+} \dot{1},$$

where we write "$\dot{1}$" for unity as an addendum. We do not write "1_r," because we shall, at a later stage, give a general definition of μ_r, in virtue of which, if μ is an inductive cardinal, μ_r will be the corresponding ordinal. This definition entails $1_r = \Lambda$, and therefore we use a different symbol "$\dot{1}$" for 1 as addendum. The symbol $\dot{1}$ is only defined in its uses, and has no significance except in a use which has been specially defined.

We define the product $\mu \dot{\times} \nu$ as the relation-number of $P \times Q$, when $\mu = \mathrm{N_0r}\text{‘}P$ and $\nu = \mathrm{N_0r}\text{‘}Q$. The product so defined obeys the associative law, and obeys the distributive law in the form

$$(\nu \dot{+} \varpi) \dot{\times} \mu = (\nu \dot{\times} \mu) \dot{+} (\varpi \dot{\times} \mu)$$

but not, in general, in the form

$$\mu \dot{\times} (\nu \dot{+} \varpi) = (\mu \dot{\times} \nu) \dot{+} (\mu \dot{\times} \varpi).$$

The latter form holds when μ, ν, ϖ are finite ordinals, as we shall prove at a later stage (*262). The commutative law also does not hold in general for ordinal addition and multiplication, but holds where finite ordinals are concerned.

The product of the numbers of the members of $C\text{‘}P$, in the order generated by P, is defined as being $\mathrm{Nr}\text{‘}\Pi\text{‘}P$, and is denoted by $\Pi\mathrm{Nr}\text{‘}P$. It will be seen that $\Pi\mathrm{Nr}\text{‘}P$ is not a function of $C\text{‘}P$, since the value of a product depends upon the order of the factors; it is also not a function of $\mathrm{Nr}``P$, unless no two members of $C\text{‘}P$ have the same relation-number. The properties of $\Pi\mathrm{Nr}\text{‘}P$ result from $*172$ and $*174$.

"μ to the νth power" is denoted by "$\mu \exp_r \nu$" and is defined as the relation-number of $P \exp Q$, where $\mu = \mathrm{N_0r}\text{‘}P$ and $\nu = \mathrm{N_0r}\text{‘}Q$. Its properties result from the propositions of $*176$ and $*177$.

$*180$. THE SUM OF TWO RELATION-NUMBERS

Summary of $*180$.

In order to define the sum of two relation-numbers, we proceed (as in $*110$) to construct a relation whose relation-number shall be the required sum. For this purpose, we put

$$P + Q = \{\downarrow (\Lambda \cap C\text{`}Q) \,\mathring{;}\, \iota \,\mathring{;}\, P\} \,\dot{\mp}\, \{(\Lambda \cap C\text{`}P) \downarrow \mathring{;}\, \iota \,\mathring{;}\, Q\} \quad \text{Df.}$$

This definition has the following merits: (1) whatever may be the types of P and Q, $\downarrow (\Lambda \cap C\text{`}Q) \,\mathring{;}\, \iota \,\mathring{;}\, P$ is of the same type as $(\Lambda \cap C\text{`}P) \downarrow \mathring{;}\, \iota \,\mathring{;}\, Q$; (2) however the fields of P and Q may overlap, and even if $P = Q$, the fields of $\downarrow (\Lambda \cap C\text{`}Q) \,\mathring{;}\, \iota \,\mathring{;}\, P$ and $(\Lambda \cap C\text{`}P) \downarrow \mathring{;}\, \iota \,\mathring{;}\, Q$ are mutually exclusive; (3) these two relations are respectively similar to P and Q. Hence it is evident that, without placing any restriction upon P and Q, we may take the relation-number of $P + Q$ as defining the sum of the relation-numbers of P and Q. Hence we put

$$\mu \dot{+} \nu = \hat{R} \{(\exists P, Q) \,.\, \mu = \mathrm{N_0r}\text{`}P \,.\, \nu = \mathrm{N_0r}\text{`}Q \,.\, R \,\mathrm{smor}\, (P + Q)\} \quad \text{Df.}$$

From this definition it follows that $\mu \dot{+} \nu$ is null unless μ and ν are homogeneous relation-numbers, but that if they are the homogeneous relation-numbers of P and Q, then $\mu \dot{+} \nu$ is the relation-number of $P + Q$.

In order to be able to deal with typically ambiguous relation-numbers, we put, as in $*110$,

$$\mathrm{Nr}\text{`}P \dot{+} \nu = \mathrm{N_0r}\text{`}P \dot{+} \nu \quad \text{Df,}$$
$$\mu \dot{+} \mathrm{Nr}\text{`}Q = \mu \dot{+} \mathrm{N_0r}\text{`}Q \quad \text{Df.}$$

The principal propositions of the present number are

$*180 \cdot 111$. $\vdash \,.\, C\text{`}(P + Q) = C\text{`}P + C\text{`}Q$

$*180 \cdot 3$. $\vdash \,.\, \mathrm{Nr}\text{`}P \dot{+} \mathrm{Nr}\text{`}Q = \mathrm{N_0r}\text{`}P \dot{+} \mathrm{Nr}\text{`}Q = \mathrm{Nr}\text{`}P \dot{+} \mathrm{N_0r}\text{`}Q$
$\qquad = \mathrm{N_0r}\text{`}P \dot{+} \mathrm{N_0r}\text{`}Q = \mathrm{Nr}\text{`}(P + Q)$

$*180 \cdot 31$. $\vdash : P \,\mathrm{smor}\, R \,.\, Q \,\mathrm{smor}\, S \,.\, \supset .\, \mathrm{Nr}\text{`}P \dot{+} \mathrm{Nr}\text{`}Q = \mathrm{Nr}\text{`}R \dot{+} \mathrm{Nr}\text{`}S$

This proposition is essential, since otherwise $\mathrm{Nr}\text{`}P \dot{+} \mathrm{Nr}\text{`}Q$ would not be a function of $\mathrm{Nr}\text{`}P$ and $\mathrm{Nr}\text{`}Q$, but would depend upon the particular P and Q.

$*180 \cdot 32$. $\vdash : C\text{`}P \cap C\text{`}Q = \Lambda \,.\, \supset .\, \mathrm{Nr}\text{`}P \dot{+} \mathrm{Nr}\text{`}Q = \mathrm{Nr}\text{`}(P \,\dot{\mp}\, Q)$

$*180 \cdot 4$. $\vdash : \exists \,!\, \mu \dot{+} \nu \,.\, \supset .\, \mu, \nu \in \mathrm{NR} - \iota\text{`}\Lambda \,.\, \mu, \nu \in \mathrm{N_0R}$

$*180 \cdot 42$. $\vdash \,.\, \mu \dot{+} \nu \in \mathrm{NR}$

$*180 \cdot 56$. $\vdash \,.\, (\mu \dot{+} \nu) \dot{+} \varpi = \mu \dot{+} (\nu \dot{+} \varpi)$

which is the associative law.

$*180 \cdot 61$. $\vdash \,.\, \mathrm{Nr}\text{`}P \dot{+} 0_r = \mathrm{Nr}\text{`}P = 0_r \dot{+} \mathrm{Nr}\text{`}P$

$*180{\cdot}71.\ \vdash : \mu, \nu \in \mathrm{NR} \,.\supset .\, C\text{“}(\mu \dotplus \nu) = C\text{“}\mu +_c C\text{“}\nu$

This proposition gives the connection of ordinal and cardinal addition. It should be observed that, in virtue of $*154{\cdot}9$, $C\text{“}\mu$ and $C\text{“}\nu$ are cardinals when μ and ν are relation-numbers.

$*180{\cdot}01.\ P + Q = \{\downarrow (\Lambda \cap C\text{‘}Q) ;\iota ; P\} \mathbin{+\!\!\!\!\uparrow} \{(\Lambda \cap C\text{‘}P) \downarrow ;\iota ; Q\}$ Df

$*180{\cdot}02.\ \mu \dotplus \nu = \hat{R}\{(\exists P, Q) \,.\, \mu = \mathrm{N_0r}\text{‘}P \,.\, \nu = \mathrm{N_0r}\text{‘}Q \,.\, R \,\mathrm{smor}\, (P + Q)\}$ Df

$*180{\cdot}03.\ \mathrm{Nr}\text{‘}P \dotplus \nu = \mathrm{N_0r}\text{‘}P \dotplus \nu$ Df

$*180{\cdot}031.\ \mu \dotplus \mathrm{Nr}\text{‘}Q = \mu \dotplus \mathrm{N_0r}\text{‘}Q$ Df

On the purpose of the definitions $*180{\cdot}03{\cdot}031$, see the remarks on the corresponding definitions in $*110$ and II T of the Prefatory Statement.

$*181$. ON THE ADDITION OF UNITY TO A RELATION-NUMBER

Summary of $*181$.

The relation-number $\dot{1}$ has, according to our definitions, no meaning in isolation, because our definitions are framed with a view to series, and a series cannot consist of one term. But we can *add* one term to a series; hence $\dot{1}$ is required as an addendum. In order to get our definitions in the most manageable form, we first construct a relation, which we call $P \,\dot{+\!\!\rightarrow}\, x$, which is such that, whenever P exists, $P \,\dot{+\!\!\rightarrow}\, x$ has one more term in its field than P; the relation-number of this relation is then defined as $\mathrm{Nr}`P \dotplus \dot{1}$. We add also a definition

$$\dot{1} \dotplus \dot{1} = 2_r \quad \mathrm{Df}$$

which is purely formal, and serves to minimize exceptions to the associative law of addition.

The definitions are closely analogous to those of $*180$. We put

$$P \,\dot{+\!\!\rightarrow}\, x = \downarrow \Lambda_x ;\iota ; P \mathbin{+\!\!\rightarrow} (\Lambda \cap C`P) \downarrow \iota`x \quad \mathrm{Df}$$

with a similar definition for $x \leftarrow\!\!\dot{+}\, P$. x and P may be of any relative types, and we have always

$$\downarrow \Lambda_x ;\iota ; P \,\mathrm{smor}\, P \,.\, (\Lambda \cap C`P) \downarrow \iota`x \sim\epsilon\, C` \downarrow \Lambda_x ;\iota ; P \quad (*181\cdot11\cdot12).$$

We put

$$\mu \dotplus \dot{1} = \hat{R}\,\{(\exists P, x) \,.\, \mathrm{N_0r}`P = \mu \,.\, R \,\mathrm{smor}\, (P \,\dot{+\!\!\rightarrow}\, x)\} \quad \mathrm{Df}$$

with a similar definition for $\dot{1} \dotplus \mu$. We also introduce definitions analogous to $*180\cdot03\cdot031$.

The principal propositions of this number are

$*181\cdot3$. $\vdash . \mathrm{Nr}`P \dotplus \dot{1} = \mathrm{N_0r}`P \dotplus \dot{1} = \mathrm{Nr}`(P \,\dot{+\!\!\rightarrow}\, x)$

$*181\cdot31$. $\vdash : P \,\mathrm{smor}\, Q \,.\supset .\, \mathrm{Nr}`P \dotplus \dot{1} = \mathrm{Nr}`Q \dotplus \dot{1}$

$*181\cdot32$. $\vdash : x \sim\epsilon\, C`P \,.\supset .\, \mathrm{Nr}`P \dotplus \dot{1} = \mathrm{Nr}`(P \,\dot{+\!\!\rightarrow}\, x)$

$*181\cdot33$. $\vdash :. \mu, \nu \,\epsilon\, \mathrm{NR} \,.\, \exists ! \mu \dotplus \dot{1} \,.\supset : \mu = \nu \,.\equiv .\, \mu \dotplus \dot{1} = \nu \dotplus \dot{1} \,.\equiv .\, \dot{1} \dotplus \mu = \dot{1} \dotplus \nu$

$*181\cdot4$. $\vdash : \exists ! \mu \dotplus \dot{1} \,.\supset .\, \mu \,\epsilon\, \mathrm{NR} - \iota`\Lambda \,.\, \mu \,\epsilon\, \mathrm{N_0R}$

$*181\cdot42$. $\vdash . \mu \dotplus \dot{1} \,\epsilon\, \mathrm{NR}$

The following propositions are formally forms of the associative law, but they need separate proof on account of the peculiarity of $\dot{1}$.

$*181\cdot54$. $\vdash : \nu \neq 0_r \,.\supset .\, (\mu \dotplus \nu) \dotplus \dot{1} = \mu \dotplus (\nu \dotplus \dot{1})$

$*181\cdot56$. $\vdash : \mu \neq 0_r \,.\supset .\, (\mu \dotplus \dot{1}) \dotplus \dot{1} = \mu \dotplus (\dot{1} \dotplus \dot{1}) = \mu \dotplus 2_r$

$*181\cdot58$. $\vdash : \mu \neq 0_r \,.\, \nu \neq 0_r \,.\supset .\, (\mu \dotplus \dot{1}) \dotplus \nu = \mu \dotplus (\dot{1} \dotplus \nu)$

***181·59.** $\vdash : \mu \neq 0_r \,.\, \nu \neq 0_r \,.\, \supset .\, (\mu \dot{+} \dot{1}) \dot{+} (\dot{1} \dot{+} \nu) = \mu \dot{+} 2_r \dot{+} \nu$

The hypotheses in the above propositions are essential.

***181·6.** $\vdash : \dot{\exists} ! P \,.\, \supset .\, C``\text{Nr}`(P \dot{\leftrightarrow} x) = \text{Nc}`C`P +_c 1$

***181·62.** $\vdash : \mu \in \text{NR} - \iota`0_r \,.\, \supset .\, C``(\mu \dot{+} \dot{1}) = C``(\dot{1} \dot{+} \mu) = C``\mu +_c 1$

These propositions give the connection with cardinals.

***181·01.** $P \dot{\leftrightarrow} x = \downarrow \Lambda_x ; \iota ; P \leftrightarrow (\Lambda \cap C`P) \downarrow \iota`x$ Df

***181·011.** $x \dot{\leftarrow} P = (\iota`x) \downarrow (\Lambda \cap C`P) \leftarrow \Lambda_x \downarrow ; \iota ; P$ Df

***181·02.** $\mu \dot{+} \dot{1} = \hat{R} \{(\exists P, x) \,.\, \text{N}_0\text{r}`P = \mu \,.\, R \,\text{smor}\, (P \dot{\leftrightarrow} x)\}$ Df

***181·021.** $\dot{1} \dot{+} \mu = \hat{R} \{(\exists P, x) \,.\, \text{N}_0\text{r}`P = \mu \,.\, R \,\text{smor}\, (x \dot{\leftarrow} P)\}$ Df

***181·03.** $\text{Nr}`P \dot{+} \dot{1} = \text{N}_0\text{r}`P \dot{+} \dot{1}$ Df

***181·031.** $\dot{1} \dot{+} \text{Nr}`P = \dot{1} \dot{+} \text{N}_0\text{r}`P$ Df

***181·04.** $\dot{1} \dot{+} \dot{1} = 2_r$ Df

Propositions concerning $x \dot{\leftarrow} P$ are omitted in what follows, since they are proved exactly as the analogous propositions concerning $P \dot{\leftrightarrow} x$ are proved.

***181·1.** $\vdash :. R (P \dot{\leftrightarrow} x) S \,.\, \equiv : (\exists y, z) \,.\, yPz \,.\, R = (\iota`y) \downarrow \Lambda_x \,.\, S = (\iota`z) \downarrow \Lambda_x \,.\, \vee .$

$[*181\cdot22] \qquad \equiv . (\exists P, x, y) . \mu = \mathrm{N_0r}`P . x \neq y . Z \in (\mathrm{N_0r}`P \dot{+} \dot{1}) \dot{+} \dot{1} .$

$[*181\cdot4] \qquad \equiv . (\exists x, y) . x \neq y . Z \in (\mu \dot{+} \dot{1}) \dot{+} \dot{1} .$

$[*24\cdot1] \qquad \equiv . Z \in (\mu \dot{+} \dot{1}) \dot{+} \dot{1} \quad (2)$

$\vdash . (2) . (*181\cdot04) . \supset \vdash . \mathrm{Prop}$

The last line in the above proof, in which $*24\cdot1$ is used, is legitimate because x and y may be of any type whatever, and therefore the fact that $\Lambda \neq \mathrm{V}$ is sufficient to establish $(\exists x, y) . x \neq y$ in the sense wanted.

$*181\cdot561$. $\mu \dot{+} \dot{1} \dot{+} \dot{1} = \mu \dot{+} (\dot{1} \dot{+} \dot{1})$ Df

This definition adopts the opposite convention to that usually adopted. But it is convenient to have $0_r \dot{+} \dot{1} \dot{+} \dot{1} = 2_r$, and also to have as much similarity as possible between the results of adding $\dot{1}$ at the beginning and end of a relation. Both reasons lead to the adoption of the above convention. (Cf. $*181\cdot57\cdot571$, below.)

$*181\cdot57$. $\vdash : \mu \neq 0_r . \supset . \dot{1} \dot{+} (\dot{1} \dot{+} \mu) = (\dot{1} \dot{+} \dot{1}) \dot{+} \mu = 2_r \dot{+} \mu$

[Proof as in $*181\cdot56$]

$*181\cdot571$. $\dot{1} \dot{+} \dot{1} \dot{+} \mu = (\dot{1} \dot{+} \dot{1}) \dot{+} \mu$ Df

$*181\cdot58$. $\vdash : \mu \neq 0_r . \nu \neq 0_r . \supset . (\mu \dot{+} \dot{1}) \dot{+} \nu = \mu \dot{+} (\dot{1} \dot{+} \nu)$ [$*161\cdot232$]

The proof proceeds in the same way as that of $*181\cdot54$.

$*181\cdot59$. $\vdash : \mu \neq 0_r . \nu \neq 0_r . \supset . (\mu \dot{+} \dot{1}) \dot{+} (\dot{1} \dot{+} \nu) = \mu \dot{+} 2_r \dot{+} \nu$ [$*161\cdot25$]

The above propositions show that, except when one of the summands is zero, the associative law holds for $\dot{1}$ just as if it were a relation-number.

The following propositions are concerned with relations to cardinal addition.

$*181\cdot6$. $\vdash : \dot{\exists} ! P . \supset . C``\text{Nr}`(P \dot{\rightarrow} x) = \text{Nc}`C`P +_c 1$

$*$182. ON SEPARATED RELATIONS

Summary of $*182$.

In this number, we have to consider, as a preliminary to the addition of the relation-numbers of a field, the properties of the relation $\overset{\frown}{\underset{;}{\downarrow}};P$, which is defined as follows. If $x ♀ y$ is any function of two arguments in the sense of $*38$, we put $\overset{\frown}{♀}‘x = x ♀ x$ Df. Thus $\overset{\frown}{\underset{;}{\downarrow}}‘Q = Q \underset{;}{\downarrow} Q$, *i.e.* $\overset{\frown}{\underset{;}{\downarrow}}‘Q = \downarrow Q;Q$. Hence $\overset{\frown}{\underset{;}{\downarrow}};P$ is the relation of $\downarrow Q;Q$ to $\downarrow R;R$ when QPR. Thus the symbol $\overset{\frown}{\underset{;}{\downarrow}};P$ is only significant when P is a relation of relations; when this is the case, $\overset{\frown}{\underset{;}{\downarrow}};P$ is the relation which results when, for every Q which is a member of $C‘P$, every member x of $C‘Q$ is replaced by $x \downarrow Q$. The result is a $\text{Rel}^2\,\text{excl}$, whose arithmetical properties serve to define the arithmetical properties of the sum of the relation-numbers of members of $C‘P$. In the next number, we shall put

$$\Sigma\,\text{Nr}‘P = \text{Nr}‘\Sigma‘\overset{\frown}{\underset{;}{\downarrow}};P \quad \text{Df.}$$

We shall put later

$$\Pi\text{Nr}‘P = \text{Nr}‘\Pi‘P$$

and we shall find

$$\Pi‘P = \dot{s};\text{Prod}‘\overset{\frown}{\underset{;}{\downarrow}};P \,.\, \text{Nr}‘\Pi‘P = \text{Nr}‘\text{Prod}‘\overset{\frown}{\underset{;}{\downarrow}};P.$$

Thus we might have dispensed with $\Pi‘P$ as a fundamental notion, using Prod instead, and putting

$$\Pi‘P = \dot{s};\text{Prod}‘\overset{\frown}{\underset{;}{\downarrow}};P \quad \text{Df.}$$

But this course is on the whole less convenient than that adopted in $*172$ and $*173$.

The notation $\overset{\frown}{♀}$ is thus required in connection with ordinal addition, where it is almost indispensable. It has besides certain minor uses. The object of the notation is to enable us to exhibit as a function of x an expression of the form $x ♀ x$, where ♀ is any descriptive double function which exists for all possible pairs of arguments. Thus for example $x \downarrow x$ is a function of x, but the notations hitherto introduced do not enable us to exhibit it in the form $R‘x$. Hence if we wish (say) to deal with the class

$$\hat{P}\{(\exists x) \,.\, x \epsilon \alpha \,.\, P = x \downarrow x\}$$

we cannot write it in the form $R‘‘\alpha$ unless we introduce a new notation. We put

$$\overset{\frown}{\downarrow}‘x = x \downarrow x$$

whence $$\hat{P}\{(\exists x) \,.\, x \epsilon \alpha \,.\, P = x \downarrow x\} = \overset{\frown}{\downarrow}‘‘\alpha.$$

We introduce the notation generally for all descriptive double functions which exist for all possible pairs of arguments. Thus "φ" in this number corresponds to "φ" in $*38$.

In the present number, we shall begin by a few propositions illustrating possible uses of the notation $\overset{\frown}{\varphi}$. Thus for example if λ is a class of relations, we have hitherto had no simple notation for expressing the class of their squares. But since $R^2 = \overset{\frown}{|}\text{‘}R$, the class of the squares of λ's is $\overset{\frown}{|}\text{“}\lambda$. The notation is, however, introduced chiefly in order to be applied to $\downarrow$ and $\underset{\cdot,}{\downarrow}$. We therefore proceed almost at once to propositions on $\overset{\frown}{\underset{\cdot,}{\downarrow}}$, and especially on $\overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P$. We have

$*182\cdot16\cdot162$. $\vdash . \overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P \in \text{Rel}^2\,\text{excl} . \overset{\frown}{\underset{\cdot,}{\downarrow}} \in 1 \to 1 . \overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P \,\text{smor}\, P$

$*182\cdot2$. $\vdash . \overset{\frown}{\underset{\cdot,}{\downarrow}}\text{‘}Q = \Pi\text{‘}(Q \downarrow Q) = \Pi\text{‘}\overset{\frown}{\downarrow}\text{‘}Q$

$*182\cdot21$. $\vdash . \overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P = \Pi{;}\overset{\frown}{\downarrow}{;}P$

We next prove ($*182\cdot27$) that if $P \in \text{Rel}^2\,\text{excl}$, then P has double likeness to $\overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P$, the double correlator being $\breve{\iota}\,|\,\text{D}$ with its converse domain limited to $C\text{‘}\Sigma\text{‘}\overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P$ ($*182\cdot26$). We then prove ($*182\cdot33$) that if $T \restriction C\text{‘}\Sigma\text{‘}P$ is a double correlator of P with Q, then $T \,\|\, \text{Cnv}\text{‘}T\dagger$ (with its converse domain limited) is a double correlator of $\overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P$ and $\overset{\frown}{\underset{\cdot,}{\downarrow}}{;}Q$, whence we deduce

$*182\cdot34$. $\vdash : P \,\text{smor smor}\, Q . \supset . \overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P \,\text{smor smor}\, \overset{\frown}{\underset{\cdot,}{\downarrow}}{;}Q$

We next proceed to prove

$*182\cdot42$. $\vdash . \Pi\text{‘}P = \dot{s}{;}\text{Prod}\text{‘}\overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P = \dot{s}{;}\text{D}{;}\Pi\text{‘}\overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P = \Pi\text{‘}\Sigma\text{‘}\overset{\frown}{\downarrow}{;}P$

The proof of this is as follows: In virtue of $*182\cdot21$ and the associative law for Π, we have

$$\dot{s}{;}\text{D}{;}\Pi\text{‘}\overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P = \Pi\text{‘}\Sigma\text{‘}\overset{\frown}{\downarrow}{;}P.$$

Now $\quad \Sigma\text{‘}\overset{\frown}{\downarrow}{;}P = P \mathbin{\dot{\cup}} I \restriction C\text{‘}P \quad (*182\cdot413)$,

and $\quad \Pi\text{‘}(P \mathbin{\dot{\cup}} I \restriction C\text{‘}P) = \Pi\text{‘}P \quad (*172\cdot51)$.

Hence our proposition results. Hence we arrive at

$*182\cdot44$. $\vdash . \text{Nr}\text{‘}\Pi\text{‘}P = \text{Nr}\text{‘}\text{Prod}\text{‘}\overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P = \text{Nr}\text{‘}\Pi\text{‘}\overset{\frown}{\underset{\cdot,}{\downarrow}}{;}P$

Finally we have some propositions showing how the notation $\overset{\frown}{\varphi}$ can be applied in cardinals. It is then applied to $\underset{,,}{\downarrow}$, instead of, as above, to $\underset{\cdot,}{\downarrow}$.

We have (*182·5·51·52) $\epsilon\, \overline{\downarrow}\, \alpha = \overset{\frown}{\underset{,,}{\downarrow}}‘\alpha \,.\, \epsilon\, \overline{\downarrow}\, “\kappa = \overset{\frown}{\underset{,,}{\downarrow}}“\kappa \,.\, \Sigma‘\kappa = s‘\overset{\frown}{\underset{,,}{\downarrow}}“\kappa$. Thus the notation of the present number might have been employed in dealing with cardinal addition (*112) instead of the notation $\epsilon\, \overline{\downarrow}\, \alpha$. The general notation $P\, \overline{\downarrow}\, x$ was, however, required for other purposes (cf. *85) and could not have been dispensed with.

In *183 we shall put

$$\Sigma \mathrm{Nr}‘P = \mathrm{Nr}‘\Sigma‘\overset{\frown}{\underset{\cdot,}{\downarrow}};P,$$

and by *182·52 we have

$$\Sigma \mathrm{Nc}‘\kappa = \mathrm{Nc}‘s‘\overset{\frown}{\underset{,,}{\downarrow}}“\kappa.$$

It will be seen that these formulae have the usual kind of analogy.

***182·01.** $\overset{\frown}{♀} = \hat{y}\hat{x}(y = x\, ♀\, x)$ Df

***182·02.** $\vdash : y\, \overset{\frown}{♀}\, x \,.\equiv.\, y = x\, ♀\, x$ [(*182·01)]

***182·021.** $\vdash .\, \overset{\frown}{♀}‘x = x\, ♀\, x$ [*182·02 . *30·3]

***182·022.** $\vdash .\, \mathrm{E}\,!\, \overset{\frown}{♀}‘x$ [*182·021 . *14·21]

***182·023.** $\vdash : \overset{\frown}{♀} \,\epsilon\, 1 \rightarrow \mathrm{Cls} : (\alpha) \,.\, \alpha \subset \mathrm{C\!\!\!I}‘\overset{\frown}{♀}$ [*182·022 . *71·166 . *33·431]

***182·03.** $\vdash .\, \overset{\frown}{|}‘R = R^2$ [*182·021 . (*34·02)]

Thus if λ is a class of relations, the class of their squares is $\overset{\frown}{|}“\lambda$.

***182·031.** $\vdash .\, \overset{\frown}{\uparrow}‘\alpha = \alpha \uparrow \alpha$ [*182·021]

***182·032.** $\vdash .\, \overset{\frown}{\downarrow}‘x = x \downarrow x$ [*182·021]

***182·033.** $\vdash .\, \dot{2} - 2_r = \mathrm{D}‘\overset{\frown}{\downarrow} = 1_s$ [*56·13 . *182·032 . *153·3]

***182·04.** $\vdash .\, \overset{\frown}{\underset{,,}{\downarrow}}‘\alpha = \downarrow \alpha“\alpha$ [*182·021 . *38·2]

Observe that in $\overset{\frown}{\underset{,,}{\downarrow}}$, we first take $\underset{,,}{\downarrow}$, and then put a circumflex over it. If we first took $\overset{\frown}{\downarrow}$, we could not then place two commas under it, because $\overset{\frown}{\downarrow}$ is a relation, not a double descriptive function, and two commas can only significantly be placed under a double descriptive function.

***182·05.** $\vdash .\, \overset{\frown}{\underset{\cdot,}{\downarrow}}‘Q = \downarrow Q;Q = Q \underset{\cdot,}{\downarrow} Q$ [*182·021 . *150·6]

The relation for the sake of which the above notation is chiefly introduced is $\overset{\frown}{\underset{\cdot,}{\downarrow}};P$, where P is a relation of relations. If P relates Q and R, then $\overset{\frown}{\underset{\cdot,}{\downarrow}};P$ relates $\downarrow Q;Q$ and $\downarrow R;R$. This is stated in the following proposition:

***182·1.** $\vdash .\, \overset{\frown}{\underset{\cdot,}{\downarrow}};P = \hat{X}\hat{Y}\{(\exists Q, R) \,.\, QPR \,.\, X = Q \underset{\cdot,}{\downarrow} Q \,.\, Y = R \underset{\cdot,}{\downarrow} R\}$
[*182·023·05 . *150·4]

***182·11.** $\vdash . C`\overset{\frown}{\underset{;}{\downarrow}};P = \overset{\frown}{\underset{;}{\downarrow}}``C`P$ [*150·22]

***182·12.** $\vdash . C`\overset{\frown}{\underset{;}{\downarrow}}`Q = \downarrow Q``C`Q = F\bar{\downarrow} Q$ [*182·05 . *150·22 . *33·5 . (*85·5)]

***182·13.** $\vdash . C``C`\overset{\frown}{\underset{;}{\downarrow}};P = F\bar{\downarrow}``C`P$ [*182·11·12]

***182·14.** $\vdash . F\bar{\downarrow} \epsilon 1 \to 1$

$*183$. THE SUM OF THE RELATION-NUMBERS OF A FIELD

Summary of $*183$.

In this number we have to define and consider the sum of the relation-numbers of the members of $C\text{‘}P$, where P is a relation of relations. Since relational sums are not commutative, we cannot define the sum of the relation-numbers of members of a class of relations λ: it is necessary that λ should be given as the field of a relation P, where P determines the order in which the summation is to be effected.

In order to avoid repetition, we replace P by $\overset{\frown}{\underset{;}{\downarrow}}\,;P$, so that if Q is a member of $C\text{‘}P$, Q is replaced by $\overset{\frown}{\underset{;}{\downarrow}}\,\text{‘}Q$, *i.e.* by $\downarrow Q;Q$. This relation is like Q, and its field has no members in common with the field of $\downarrow R;R$, unless $Q = R$. Hence we are led to the following definition:

$*183\cdot01$. $\Sigma\text{Nr}\text{‘}P = \text{Nr}\text{‘}\Sigma\text{‘}\overset{\frown}{\underset{;}{\downarrow}}\,;P$ Df

This definition is analogous to $*112\cdot01$, as appears from $*182\cdot52$, and the propositions of the present number are analogous to some of the propositions of $*112$.

We have not merely

$*183\cdot11$. $\vdash : P \text{ smor smor } Q \,.\supset.\, \Sigma\text{Nr}\text{‘}P = \Sigma\text{Nr}\text{‘}Q$

but also

$*183\cdot15$. $\vdash : \overset{\frown}{\underset{;}{\downarrow}}\,;P \text{ smor smor } \overset{\frown}{\underset{;}{\downarrow}}\,;Q \,.\supset.\, \Sigma\text{Nr}\text{‘}P = \Sigma\text{Nr}\text{‘}Q$

which is a proposition with a weaker hypothesis than that of $*183\cdot11$ (cf. note to $*182\cdot34$).

Important propositions in this number are

$*183\cdot13$. $\vdash : P \in \text{Rel}^2\text{excl} \,.\supset.\, \text{Nr}\text{‘}\Sigma\text{‘}P = \Sigma\text{Nr}\text{‘}P$

$*183\cdot2$. $\vdash : \Sigma\text{Nr}\text{‘}P = 0_r \,.\equiv.\, \dot{\Sigma}\text{‘}P = \dot{\Lambda}$

I.e. a sum is only zero when there is no summand except (at most) zero. (Cf. $*162\cdot4\cdot45$.)

$*183\cdot25$. $\vdash .\, \Sigma\text{Nr}\text{‘}P \underset{;}{\downarrow}\,;Q = \text{Nr}\text{‘}(Q \times P)$

$*183\cdot26$. $\vdash :.\, \text{Mult ax} \,.\supset : P \in \text{Nr}\text{‘}R \,.\, C\text{‘}P \subset \text{Nr}\text{‘}S \,.\supset.\, \Sigma\text{Nr}\text{‘}P = \text{Nr}\text{‘}(R \times S)$

This proposition connects addition and multiplication.

$*183\cdot31$. $\vdash : P \mathbin{\ddagger} Q \,.\supset.\, \Sigma\text{Nr}\text{‘}(P \downarrow Q) = \text{Nr}\text{‘}P \dotplus \text{Nr}\text{‘}Q$

This proposition connects the two kinds of addition. We have also

$*183\cdot33$. $\vdash : \dot{\exists} ! P \,.\, Z \sim\in C\text{‘}P \,.\dot{\supset}.\, \Sigma\text{Nr}\text{‘}(P \rightarrow\!\!\!\!+ Z) = \Sigma\text{Nr}\text{‘}P \dotplus \text{Nr}\text{‘}Z$

The associative law of addition in a very general form is

$*183{\cdot}43.\quad \vdash : P \in \mathrm{Rel}^2\,\mathrm{excl}\,.\supset .\,\Sigma\mathrm{Nr}\text{‘}\Sigma\,;\,\overset{\frown}{\underset{\cdot\,;}{\downarrow}}\,\dagger\,;P = \Sigma\mathrm{Nr}\text{‘}\Sigma\text{‘}P$

Finally the connection of ordinal and cardinal addition is given by

$*183{\cdot}5.\quad \vdash : C \restriction C\text{‘}P \in 1 \to 1\,.\supset .\,C\text{“}\Sigma\mathrm{Nr}\text{‘}P = \Sigma\mathrm{Nc}\text{‘}C\text{“}C\text{‘}P$

$*183{\cdot}01.\quad \Sigma\mathrm{Nr}\text{‘}P = \mathrm{Nr}\text{‘}\Sigma\text{‘}\overset{\frown}{\underset{\cdot\,;}{\downarrow}}\,;P \quad \mathrm{Df}$

$*183{\cdot}1.\quad \vdash .\,\Sigma\mathrm{Nr}\text{‘}P = \mathrm{Nr}\text{‘}\Sigma\text{‘}\overset{\frown}{\underset{\cdot\,;}{\downarrow}}\,;P \quad [(*183{\cdot}01)]$

$*183{\cdot}11.\quad \vdash : P\,\mathrm{smor\,smor}\,Q\,.\supset .\,\Sigma\mathrm{Nr}\text{‘}P = \Sigma\mathrm{Nr}\text{‘}Q$

Dem.

$*184$. THE PRODUCT OF TWO RELATION-NUMBERS

Summary of $*184$.

The propositions of this number are for the most part analogous to those of the propositions of $*113$ which are concerned with $\mu \times_0 \nu$. Those of $*113$ which are concerned with $\alpha \times \beta$ have their analogues in $*166$. We put

$*184{\cdot}01$. $\mu \dot{\times} \nu = \hat{R}\{(\exists P, Q) . \mu = \mathrm{N_0r}`P . \nu = \mathrm{N_0r}`Q . R \operatorname{smor} (P \times Q)\}$ Df

$*184{\cdot}02$. $\mathrm{Nr}`P \dot{\times} \nu = \mathrm{N_0r}`P \dot{\times} \nu$ Df

$*184{\cdot}03$. $\mu \dot{\times} \mathrm{Nr}`Q = \mu \dot{\times} \mathrm{N_0r}`Q$ Df

We prove that $\mu \dot{\times} \nu$ is only zero when one of its factors is zero ($*184{\cdot}16$); we prove the associative law ($*184{\cdot}31$), and the distributive law in the forms

$*184{\cdot}33$. $\vdash : P \in \mathrm{Rel}^2 \mathrm{excl} . \supset . \Sigma \mathrm{Nr}`P \dot{\times} \mathrm{Nr}`R = \Sigma \mathrm{Nr}`(\times R) ; P$

$*184{\cdot}35$. $\vdash . (\nu \dot{+} \varpi) \dot{\times} \mu = (\nu \dot{\times} \mu) \dot{+} (\varpi \dot{\times} \mu)$

and we prove $2_r \dot{\times} \mu = \mu \dot{+} \mu$ ($*184{\cdot}4$). Also we extend the distributive law to the case where one of the summands is $\dot{1}$, *i.e.* we prove

$*184{\cdot}41$. $\vdash : \nu \neq 0_r . \supset . (\nu \dot{+} \dot{1}) \dot{\times} \mu = (\nu \dot{\times} \mu) \dot{+} \mu$

$*184{\cdot}42$. $\vdash : \nu \neq 0_r . \supset . (\dot{1} \dot{+} \nu) \dot{\times} \mu = \mu \dot{+} (\nu \dot{\times} \mu)$

and the connection of cardinal and ordinal multiplication is given by

$*184{\cdot}5$. $\vdash : \mu, \nu \in \mathrm{NR} . \supset . C``(\mu \dot{\times} \nu) = C``\mu \times_0 C``\nu$

$*184{\cdot}01$. $\mu \dot{\times} \nu = \hat{R}\{(\exists P, Q) . \mu = \mathrm{N_0r}`P . \nu = \mathrm{N_0r}`Q . R \operatorname{smor} (P \times Q)\}$ Df

$*184{\cdot}02$. $\mathrm{Nr}`P \dot{\times} \nu = \mathrm{N_0r}`P \dot{\times} \nu$ Df

$*184{\cdot}03$. $\mu \dot{\times} \mathrm{Nr}`Q = \mu \dot{\times} \mathrm{N_0r}`Q$ Df

$*184{\cdot}1$. $\vdash : R \in \mu \dot{\times} \nu . \equiv . (\exists P, Q) . \mu = \mathrm{N_0r}`P . \nu = \mathrm{N_0r}`Q . R \operatorname{smor} (P \times Q)$
[($*184{\cdot}01$)]

The proofs of the following propositions are omitted, since they are analogous to those of the corresponding propositions of $*113$.

$*184{\cdot}11$. $\vdash : \exists ! \mu \dot{\times} \nu . \supset . \mu, \nu \in \mathrm{N_0R} . \exists ! \mu . \exists ! \nu$

*185. THE PRODUCT OF THE RELATION-NUMBERS OF A FIELD

Summary of *185.

The subject of this number is analogous to part of the subject of *114. The propositions concerned are immediate consequences of previously proved properties of $\Pi{}^{\backprime}P$, and offer no difficulty of any kind.

$*186$. POWERS OF RELATION-NUMBERS

Summary of $*186$.

For "μ to the νth power," where ordinal powers are concerned, we use the notation "$\mu \exp_r \nu$." We cannot use "μ^ν" or "$\mu \exp \nu$" because these have been already used for cardinals and classes ($*116$). We therefore put a suffix r to "exp" to show that it is *relational* powers that we are dealing with. We put

$$\mu \exp_r \nu = \hat{R}\{(\exists P, Q) \,.\, \mu = \mathrm{N_0r}`P \,.\, \nu = \mathrm{N_0r}`Q \,.\, R \operatorname{smor} (P \exp Q)\} \quad \mathrm{Df}$$

The following are the principal propositions of this number:

$*186{\cdot}2$. $\vdash : \mu \in \mathrm{N_0R} \,.\, \supset \,.\, 0_r \exp_r \mu = 0_r \,.\, \mu \exp_r 0_r = 0_r$

We do not have $\mu \exp_r 0_r = 1$, because there is no ordinal 1.

$*186{\cdot}21$. $\vdash . \mu \exp_r 2_r = \mu \dot{\times} \mu$

$*186{\cdot}22$. $\vdash . \alpha \exp_r (\beta \dot{+} \dot{1}) = (\alpha \exp_r \beta) \dot{\times} \alpha$

$*186{\cdot}23$. $\vdash . \alpha \exp_r (\dot{1} \dot{+} \beta) = \alpha \dot{\times} (\alpha \exp_r \beta)$

$*186{\cdot}14$. $\vdash : \nu \neq 0_r \,.\, \varpi \neq 0_r \,.\, \supset \,.\, \mu \exp_r (\nu \dot{+} \varpi) = (\mu \exp_r \nu) \dot{\times} (\mu \exp_r \varpi)$

$*186{\cdot}15$. $\vdash : \varpi \subset \mathrm{Rl}`J \,.\, \supset \,.\, \mu \exp_r (\varpi \dot{\times} \nu) = (\mu \exp_r \nu) \exp_r \varpi$

$*186{\cdot}31$. $\vdash :. \mathrm{Mult\,ax} \,.\, \supset : \mu, \nu \in \mathrm{NR} - \iota`\Lambda \,.\, P \in \mathrm{Rel^2\,excl} \cap \mu \,.\, C`P \subset \nu \,.\, \supset \,.$
$\Pi \mathrm{Nr}`P = \mu \exp_r \nu$

which connects exponentiation with multiplication.

$*186{\cdot}4$. $\vdash . \mathrm{Nr}`P_{\mathrm{df}} = 2_r \exp_r (\mathrm{Nr}`P)$ (cf. $*177$)

$*186{\cdot}5$. $\vdash : \mu, \nu \in \mathrm{N_0R} \,.\, \nu \neq 0_r \,.\, \supset \,.\, C``(\mu \exp_r \nu) = (C``\mu)^{C``\nu}$

which connects ordinal and cardinal exponentiation.

$*186{\cdot}01$. $\mu \exp_r \nu = \hat{R}\{(\exists P, Q) \,.\, \mu = \mathrm{N_0r}`P \,.\, \nu = \mathrm{N_0r}`Q \,.\, R \operatorname{smor} (P \exp Q)\}$ Df

$*186{\cdot}02$. $(\mathrm{Nr}`P) \exp_r \nu = (\mathrm{N_0r}`P) \exp_r \nu$ Df

$*186{\cdot}03$. $\mu \exp_r (\mathrm{Nr}`Q) = \mu \exp_r (\mathrm{N_0r}`Q)$ Df

$*186{\cdot}1$. $\vdash : R \in \mu \exp_r \nu \,.\, \equiv \,.\, (\exists P, Q) \,.\, \mu = \mathrm{N_0r}`P \,.\, \nu = \mathrm{N_0r}`Q \,.\, R \operatorname{smor} (P \exp Q)$
[($*186{\cdot}01$)]

$*186{\cdot}11$. $\vdash . \exists ! \mu \exp_r \nu \,.\, \supset \,.\, \mu, \nu \in \mathrm{N_0R} \,.\, \mu, \nu \in \mathrm{NR} - \iota`\Lambda$

$*186{\cdot}111$. $\vdash : \sim(\mu, \nu \in \mathrm{N_0R}) \,.\, \supset \,.\, \mu \exp_r \nu = \Lambda$

$*186{\cdot}12$. $\vdash : R \in \mu \exp_r \nu \,.\, \equiv \,.\, (\exists P, Q) \,.\, \mu = \mathrm{N_0r}`P \,.\, \nu = \mathrm{N_0r}`Q \,.\, R \operatorname{smor} P^Q$

PART V

SERIES

SUMMARY OF PART V

A RELATION is said to be *serial*, or to generate a series, when it possesses three different properties, namely (1) being contained in diversity, (2) transitiveness, (3) connexity, *i.e.* the property that the relation or its converse holds between any two different members of its field. Thus P is a serial relation if (1) $P \subseteq J$, (2) $P^2 \subseteq P$, (3) $x, y \in C'P \,.\, x \neq y \,.\, \supset_{x,y} : xPy \,.\, \vee \,.\, yPx$. The third characteristic, that of connexity, may be written more shortly

$$x \in C'P \,.\, \supset_x \,.\, \overrightarrow{P}'x \cup \iota'x \cup \overleftarrow{P}'x = C'P,$$

i.e.

$$x \in C'P \,.\, \supset_x \,.\, \overleftrightarrow{P}'x = C'P,$$

using the notation of $*97$; and this, in virtue of $*97{\cdot}23$, is equivalent to

$$\overleftrightarrow{P}''C'P \in 0 \cup 1.$$

In virtue of $*50{\cdot}47$, the first two characteristics are equivalent to

$$P \dot{\cap} \breve{P} = \dot{\Lambda} \,.\, P^2 \subseteq P.$$

When $P \dot{\cap} \breve{P} = \dot{\Lambda}$, we say that P is "asymmetrical." Thus serial relations are such as are asymmetrical, transitive, and connected.

It might be thought that a serial relation need not be contained in diversity, since we commonly speak of series in which there are repetitions, *i.e.* in which an earlier term is identical with a later term. Thus, *e.g.*

$$a,\ b,\ c,\ a,\ e,\ f,\ b,\ g,\ h$$
